As it has been conclusively shown how that the "bundle" of balloons moves faster than the component dirigibles singly, the radius of action, or the fuel supply carried, may be much increased by making the power plant weaker than the sum of the component dirigibles' aggregate power. A further decrease in power (without much lowering the speed) and in the load carried, will secure the additional advantage that the ship may be floated with partially inflated gas cells, and, supported by its aeroplane rudders, allowed to ascend to the highest levels.

The larger the volume of the dirigible, the smaller is its surface in proportion to its lift, or to the gas carried. If the air space between the outer skin or envelope and the interior gas bags, which has proved so useful in Zeppelin airships, is introduced into the design of a mammoth dirigible, it will completely eliminate all troubles arising from variations in the lifting power caused by a change in temperature under the influence of the sun's rays, or of darkness or shadows. Furthermore, it is obvious that the adventitious load which may collect upon a dirigible in the form of rain, snow or sleet, or ice, is proportional to the surface area. If this area is small as compared with the lift of the balloon, the effect of such unwelcome ballast is correspondingly reduced, and the mammoth dirigible approaches in this respect the sea-going vessel, which is practically quite unaffected under similar conditions. The numerous propellers will incidentally serve a useful function by blowing a strong blast of air along the surface of the car, whereby any snow or rain will be swept off. An obvious improvement which suggests itself would be to heat the air space around the gas bags with the exhaust from the motors, thus preventing ice from forming upon the outer envelope. By flushing this space with hot exhaust gas, or cool air, as the case may be, the balloon gas within may be rendered entirely independent of outside influences. The volume of the air space is comparatively very small, and there is enough exhaust to inflate it in a few minutes. The task is much facilitated through the fact that all the motors are in comparatively close proximity to the outer envelope, and are distributed more or less evenly over the whole structure. This device should be of great assistance in adding to the lifting power of the mammoth dirigible. For it will keep the temperature of the gas much above that of the frigid air at an altitude of three miles, for example. It is, of course, well understood that this circumstance increases the buoyancy.

One objection which perhaps arises in the reader's mind, is the danger from fire. As a matter of fact, the problem of guarding against this is no greater than that daily faced in coal mines. The Davy wire gauze screen must be used to the fullest extent of its possibilities. Its weight need be but small. First and foremost the carburetors must be inclosed in absolutely proof gauze baskets. In addition to this the entire engine room should be similarly protected. All electric insulations must be as perfect as those near the powder magazine of a warship. Exhaust tubes must be water-jacketed, asbestos-lined and inclosed in wire gauze, and the same applies to the mufflers. The gasoline tanks should be placed at the very core of the ship, far from the engines, and the fuel should be forced under pressure through slender but strong tubes of annealed copper, which would stand any vibration or shock. All joints must be welded by the autogenous process. These tubes run through small tunnels continuously flushed by a current of fresh air. The principal safeguard against fire is the elaborate ventilation system which instantly dissipates any escaping gas or gasoline fumes at any portion of the interior. The weight of these safety devices is but trifling. In point of ventilation the airship has this great advantage over the ship traveling by water, that it receives the relative wind always from the same quarter and with a never lagging force while under way. The mechanical blowers receiving the air (from the vents) already partially compressed are thus relieved of a considerable portion of their work. When the balloon is stationary the main motors become available for driving the ventilating engines. At the moorings in the harbor compressed air for the safety ventilation is taken from fixed mains through a flexible hose. A great air harbor of the future will include a blower plant similar to that of a foundry.

The complicated system for the circulation of water, air, steam and for the distribution of electricity, so familiar on large ocean vessels of our day, is not only a convenience, but becomes a vital necessity in the dirigible of the future. This safety ventilation, on the other hand, tends to increase the gas losses. If the entire structure were one great gas space, the volume of gas would be so great in proportion to the surface, and the outer envelope so thick, that the loss would be insignificant. The captive balloon at the Paris Exposition, with 25,000 cubic meters capacity, has proved this. But in the practical airship here described, the proportion of the total surface of the gas cells to their volume is just as great as for a single one of the individual cells of which it is composed, nor are the walls any thicker. However, the gas loss by slow filtration through the envelope is even in the balloons of the present day more than compensated for by reduction in fuel weight, and as a matter of fact, troublesome gas losses occur only through expansion by ascension or under the influence of the sun's rays. This last source of loss is completely overcome in the dirigible of the future. In order to avoid having to blow off gas when the fuel supply (ballast) runs low, the gas itself should be used as fuel, and not run to waste.

The cost of housing a very large airship would be a serious difficulty. But there is no reason why a balloon should not be moored in the open, provided that two conditions were complied with, both of which are fulfilled by the mammoth dirigible. The first requirement is sufficient toughness of the outer envelope, so that neither rain nor snow nor sun could harm it. The second condition is sufficient strength of structure to withstand the pressure of a gale. (As the air offers nowhere a real harbor in the same sense as a sheet of water, but only open anchorages, in an excessively severe storm an airship must simply take the same steps as would be adopted by a steamer in the open sea—raise anchor and get up steam.) The second condition is obviously fulfilled if the normal speed of the ship is equal to that of a storm. The anchor cable must of course be attached to the bow, in such way that the entire frame acts toward tension stresses as an elongation of a cable. In a severe hurricane propellers can be started to ease the strain on the cable. The strength of the structure in proportion to its bow area and the vent system provide ample margins of safety. Absolute safety will be secured by anchoring a ship to a high tower, around which it would swing freely as a weather vane. But the Zeppelin method of holding the bow close to the ground and allowing the stern to float and swing, relying on the jamming of the wind between the hull and the ground to prevent a fatal collision with the ground, also holds great promise and has the advantage of simplicity. It certainly has proved effective in very high winds. After leaving the dockyards a mammoth dirigible must remain afloat as steadily as a ship in order to be manageable. This problem presents no difficulty at the present time, being solved in the Parseval airships by the daily injection of small quantities of fresh gas. If this is effective in an airship with a single gas space, it would be even more so in a multi-cellular ship, in which the gas in the cells may be completely renewed by emptying and inflating cells alternately without decreasing the flotation more than can be readily allowed for in the harbor. In the same way entire gas cells may be removed and new ones inserted while the ship remains afloat. It may even be possible to devise a method for eliminating the air from deteriorated gas, extracting the latter from the cells and returning it to them regenerated.

A mammoth dirigible provides all the comforts of a steamer. Staterooms would be located in the interior, dining saloons, kitchens, stores, etc., near the bottom, promenade decks on the top. It is interesting to note that elevators weigh less than stairs, especially those built on the plan of modified rope ladders. Furthermore, monorails with light cradle frames running over them weigh less than passageways with walking floors. A new system of rapid intercommunication must be introduced on board the dirigible of the future to save weight and insure comfort. Incidentally it would prevent the sudden shifting toward one point of the weight of many passengers. No doubt the mammoth dirigible will prove weaker if it collides with the ground than a dirigible of to-day. But similar objections hold in the case of ships on the water, and still their size is increasing at a rate which makes us smile at the "Great Eastern" of years ago. A rowboat is but little damaged by a collision. If the "Titanic" should drift at slow speed against a rock, its steel plates would crumble like paper. If the parts of a steamer are stronger than those of a dirigible, the total weight of a steamer, which determines the crushing force, is also greater in the same proportion. Ships are placed under much the same circumstances on the water and in the air, and in either case must be jealously guarded against any possible collision. In the case of a dirigible, the danger is greatest while it is being handled near the ground, but the mammoth dirigible, after it is once launched from the dockyard shed (in absolutely quiet air, of course, as at the recent launching of the English naval dirigible), does not need to be handled near the ground because it does not enter a shed. It may be moored to a tower or upon a broad unobstructed plain by its own engine power, which is great enough to control very heavy winds. This means that with its propellers the ship can be held motionless against any wind. With the aid of the rudders even sudden gusts may be resisted, inasmuch as they cannot produce any jerky motions in a body of such large bulk. (To anchor in a severe storm is as inadvisable as it would be on the water—storms must be outridden.) The operation of landing on a plain would involve some very nice work of the horizontal rudders while the ship is driven energetically with reversed engines. The bow is dipped down toward the ground, anchor is cast, and the engines are reversed to their normal motion to ease the jerk on the anchor. Then the engines are reversed again and at the same time the anchor is hauled in. In this way the anchor is made to bite the ground so firmly that it will still hold even after the cable has been shortened from 20 to 30 feet (this terminal portion of the cable being made twice as strong as the rest). The propellers are kept revolving until the anchor has been permanently secured. A flexible "gang plank" is dropped to the ground from the bow, while the ship's stern remains floating high in the air. Very similar maneuvering has been successfully used on the Zeppelins. Keeping some of the propellers revolving with reversed motors is of course an excellent way of guarding against any collision of the bow with the ground, even in heavy and irregular gusts, while thus anchored.

If the airship is to be made fast to a tower it must be skillfully brought near the top of the tower, best by drifting past with the wind, at a moment when the wind is fairly steady. Several attempts may be necessary before success is attained. In this case also it may be a good plan to keep some of the propellers revolving in the reverse direction.

Fantastic as this mental picture of the giant airship of the future may appear to us with our present notions of aerial navigation, when we think of our sky scrapers and the 50,000-ton leviathans plying the sea, it appears that the picture here drawn is well in accord with the modern tendency, and in fact it is to be expected that the 1,000-foot airship will make its appearance before very long.

The Opium Problem in Parts of China

SOME unexpected results are found from the movement against the production of opium in China. In the Yunnan, one of the provinces where opium was produced in large quantities and at a low price and where a great deal of it was consumed, it appears that the poppy is no longer cultivated, owing to the recent measures, and the poppy fields have quite disappeared, according to the statements made by Drs. Talbot and Rigaud. However, this has had a disastrous effect on the honey culture of the region. In fact, the honey from Yunnan was renowned for its quality, but as the bees find no more flowers, the production of honey is stopped as well. The new crops which replace the poppy, such as wheat or peas, are not such as will give a honey yield as well. On another side of the question, it appears that the habits of the population are not suppressed by the present legislation, as some supposed would be the case, but according to Dr. Talbot, opium-smoking is again on the increase.

Audibility of the Aurora

To the Editor of the SCIENTIFIC AMERICAN:

If your paper is interested in the above question, you can easily set Prof. Trombolt right by sending one of your staff to St. John, N. B., or Halifax, N. S., during the fall months, or better in the early winter, and he will then hear the sounds from the aurora, and perhaps it is possible to phonograph them.

I have heard those sounds thousands of times, particularly on very cold and clear nights, while living in St. John thirty to forty years ago.

They sound like the swishing of switches through the air, and at times like the detonations of small fire crackers; at other times they sound like distant musketry, as if firing away from the heaven.

The sounds, as I remember them, do not appear unless the aurora is moving, which happens often enough for observation.

New York city. R. FLAHERTY.

A Plan to Protect the Poor Inventor

To the Editor of the SCIENTIFIC AMERICAN

As I believe that a meeting of the International Congress of the Union for the Protection of Industrial Property is soon to take place, I take the liberty to submit some suggestions that I trust will be useful and worthy of consideration.

It is a well-known opinion among a majority of manufacturers and inventors of limited or liberal means, that the term of a patent is at present too short. It is also well known that the protection as to right of priority of invention is not as perfect as it should be. The manufacturer, when he files an application for a patent, has the capital necessary to put the article on the market and to fight through the courts not only the infringers but such patents as are in the way, even though they do not fully infringe. The inventor of limited means, at such times, lacks perhaps the experienced experts of the manufacturers that are ever ready to give any testimony in litigation to prove priority of invention or other facts; and at the best all that said inventor can secure, with his more honest but poorly defended evidence, is of very little importance and hardly satisfactory.

To remedy the above two conditions I suggest:

1. That the term of a patent be extended to twenty years.

2. That the first and final patent fees be $20 each.

3. That each patent thus issued shall be renewable for ten more years upon the payment of a tax of $200.

4. That a second renewal be allowed to each patent upon the payment of a tax of $300.

5. That *each* inventor, to prove his priority of invention, be allowed to prepare his own rough sketches in secret, as the development of the invention progresses, said secret sketches to be presented for sealing to a judge or other high official in the district in which the inventor is located at the time.

6. That the sealing before the judge or official be made under oath after the payment of a tax of $1, the sealing being of such a prescribed character that it will not disclose the nature of the invention at the time, and will prevent interference with the contents of the package after sealing, and that will also indicate the date of sealing, the district where the sealing took place, and the name and position of the official sealing said secret sketches, which may be identified hereafter by the term "Priority Proofs."

7. That the inventor be allowed the option of holding said priority proofs or of filing them in a special department in the Patent Office.

8. That said priority proofs shall not be examinable, when filed, until the time of the filing of the formal patent application, and then only after a request to that effect by the applicant.

9. That an inventor be allowed to secure as many such priority proofs as he may deem advisable.

10. That the presentation of the earliest or of all of said priority proofs, secured for one invention, under the proper seals, shall be considered as *prima facie* evidence in any dispute of priority or technicality arising during the examination or litigation of any patent case.

It can be seen from the above that if A has an invention fairly well defined in its form, but still subject to a series of developments, he can under oath secure, without disclosing his invention, a priority proof under the seal, date and signature of a judge or other high official, and thereafter follow the development of his invention for a period of time until it is ready for the formal filing at the Patent Office, the inventor feeling all this time his work is under protection of priority.

This will also help many inventors that cannot afford at the time the expenses of a patent application, giving them the opportunity to save or raise such moneys after they have sealed their priority proofs and assured their inventive rights.

The *priority proofs* are not examinable, and, except for the filing, they will cause no extra work to the Patent Office, until requested by an applicant filing a formal patent application.

The priority proofs will tend to eliminate the abuses of expert testimony, at present experienced in certain patent litigations.

Another point I wish to call to your attention is the lack of patent protection accorded Americans in foreign countries under their present laws.

While we issue a patent for seventeen years without yearly taxes except the initial fees of $35, most of the foreign countries issue patents for fifteen years for an initial fee like our own, but subject to a yearly tax on each patent as well as working clause.

Both of the above features are objectionable to the interests of the American inventor and manufacturer, and there is no reason why we should allow the privileges under our laws to the foreign patentees whose countries refuse to allow similar privileges to our inventors.

The loss to our ingenuities and industries is pronounced. An inventor having a valuable invention, patents the same abroad. In trying to sell it, when he cannot manufacture it himself, he experiences much delay at the hands of certain manufacturers, with the result that the working time limit comes right upon him. After such time, his patent being belittled in value, can be and is fought, and declared null and void, and thereafter every manufacturer abroad reaps a harvest upon the hard labors of American ingenuity.

In consequence, the American finds it difficult to control many an article in the foreign markets, and very often hard to compete with similar productions of such market.

Even manufacturers that, for certain reasons, have found it impossible to manufacture their patented articles abroad, have had their patents abrogated and lost considerably thereby.

At the same time, a foreign manufacturer can secure a patent in this country under the liberal system, manufacture the article in his own country, at low cost of labor, and importing it here and selling it at a lower cost and better profit than in his own country.

This also explains, in part, why a number of the foreign countries are not so often subject to the periodical industrial retardations that are so current in this country.

The inventor with limited means possibly finds himself, after delayed negotiations or litigations with foreign manufacturers, unable to pay the taxes, and the loss of the patent is the result.

It would be a very patriotic and conservative policy on your part to urge legislation to the effect:

1. That the citizens of a foreign country, not residing in the United States, and whose country issues patents to American citizens under the time limit clause and yearly tax clause, shall be able to receive and hold their patent rights in this country only upon working their invention in this country within three years from the time of the issue of the patent and upon the payment of a yearly tax of $20, beginning from the second year.

2. That upon the failure of the patentee to work his invention within the prescribed limit of time, his patent shall be open to contestation and annulment.

3. That upon the non-payment of the yearly tax, said patent shall be declared null and void.

4. That the citizens of such foreign countries as accord to the American inventor the same privileges that are accorded by the United States laws to its own citizens, shall be exempt from the working clause and the yearly taxation.

These points when brought to the attention of the foreign delegates at the coming convention may prompt them to suggest or formulate modifications in their laws as to the Union of Industrial Property clauses that would be more favorable to the American inventor and manufacturer.

The foreign countries can easily suspend the working clauses and yearly taxes, and if they need the money from such taxes they can make it up by increasing the initial filing fees.

They can easily realize that by removing the above objectionable clauses from their laws they will encourage invention to such an extent that the initial fees of the increased number of patent applications will more than compensate for the change.

A great majority of the American inventors would, under the new conditions, file foreign applications, while at present they do not care to do so because of the existing uncertainties.

I trust that these suggestions will receive the approval of a great many inventors, and therefore will attempt to give the American inventive public an opportunity to take up the subject and debate upon the merits and demerits of said suggestions.

It is the cause of the inventor with limited means that must be progressed, for they are the pioneers in all great things, as is evidenced by the manufacturers looking to them for meritorious inventions more than to their own experimental staffs.

The time is now ripe for such a move on your part, and I therefore urge you to give due attention to the matter, presented, as it is, as a conclusion of views given by inventors, manufacturers, and attorneys.

Electric Fans for the Sick

To the Editor of the SCIENTIFIC AMERICAN.

A subscriber to your paper has written us, calling our attention to a short article in your issue of July 22nd entitled "Electric Fans for the Sick," the same referring to the practice of The Electric Supply Company at DeKalb, Ills. This gentleman it seems, had heard of the order issued to all of the electric properties under the control and management of H. M. Byllesby & Co. early in July, directing that electric fan service be furnished free to all invalids who were unable to pay for the service, upon presentation of the proper certificate from attending physician. This order meant that in 106 cities and towns in the West, Middle West and South, any indigent sick person might obtain fan service during the hot months absolutely free, the local company not only providing the fan, but extending the service lines and temporary interior wiring where necessary, and furnishing current. This action has resulted in a great deal of favorable comment both by press and public, and in nearly every city from six to eight fans were immediately placed in commission under the terms mentioned.

The idea so far as we can learn originated with the electric light and power company at Rochester, New York. As soon as Mr. Arthur S. Huey, vice-president of H. M. Byllesby & Co., heard of it he immediately issued the order described above, which directly reaches invalids in a total population of nearly one million people.

H. M. BYLLESBY & CO.
By W. H. HODGE, Publicity Manager.

The Postal Aeroplane

REPORTS come from England and France that the official postal aeroplane for the rapid transport of mail matter is soon to become an actual reality. On August 13th Pierre Vedrines, the veteran aviator, winner of the prize for his recent notable aerial trip from Paris, France, to Madrid, Spain, made one of ten flights to demonstrate the possibility of an aero mail service. This flight was most successful. He left Issy-les-Moulineaux near Paris with mail aboard at 5.07 P. M. and reached Deauville, near Trouville, 112 miles from Issy, at 6.50 P. M., or one hour and forty three minutes, or at the rate of a trifle over sixty five miles an hour. The time of the fast express train going the same distance is 3 hours and 12 minutes, or 1 hour and 19 minutes longer.

On the way Vedrines dropped letter packages at Mantes-sur-Seine, Evreux and Lisieux. It is said he was paid five hundred dollars for the flight, which would average a trifle less than $5 per mile.

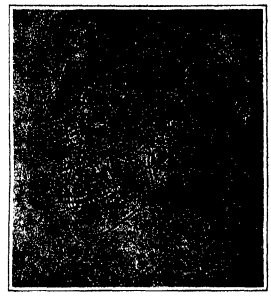
In London the Post Office Department is making preparations for the early inauguration of a special aerial postal service to be carried on between London and Windsor a distance of twenty-one miles. Special aerial post boxes are to be placed in public places, in which letters for this service must be deposited the same as in ordinary boxes. Collections by carriers will be made in the usual way and deposited in a central location, from which the aeroplane will depart. There the mail will be placed in sealed letter bags and the latter strapped on to the aeroplane. The flight to Windsor will occupy about half an hour. From Windsor the mail will be forwarded by train to its intended destination. King George has given permission for space in Windsor Park to try out this experiment, which is to last a week and perhaps longer.

The time is now at hand when it would be in the line of progress for congress to make appropriations for an experimental aerial postal service between two cities, as for example between New York city and Philadelphia, providing for hourly flights each way. Operating at a speed maintained by Vedrines in the Paris experiment, a letter could be sent from New York in the morning to Philadelphia and the sender receive an answer in the afternoon.

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

The Man of Glacial Europe



THE man who can point to a line of distinguished ancestors from whom he is *descended*, usually sees in the fact an object of self gratification. It would seem more logical if he took pride in showing that he has *ascended* from his progenitors, though perhaps he might hesitate to decorate the walls of his dwelling with the portraits of such rude forbears as are shown in our accompanying illustrations Dr Keith writing for the *Illustrated London News*, presents as follows the most modern views with regard to the earliest traces discovered of man's habitation upon this earth

In recent years our knowledge of the human in habitants of Europe during the Glacial period has *increased rapidly* It is over fifty years since the *first* trace of him was found at Neanderthal, in South Ger many, before that, although it is only recently we have got to know the fact, he had been found in Gibraltar the skull then found, on the whole the most perfect yet discovered, is in the Museum of the Royal College of Surgeons of England In recent years three wonderfully instructive skeletons have been found in the southwest of France, in the valley of the Dordogne, and have attracted much attention Remains of the Neanderthal man have also been found in Belgium—the famous skulls of Spy—and in the southeast of Europe—at Krapina, in Croatia And now, thanks to the researches of the Société Jersiaise, remains of this race have been found in Jersey In a cave in the cliffs of St Brelade's Bay, on the south coast of the island, his hearths, his characteristic flint implements, and his unmistakable teeth have been discovered

A recently rich man must find occasionally, when proper investigations are made, that his remote an cestors are infinitely older and more respectable than he had formerly reason to believe It is becoming more and more apparent that this is the case as regards modern man The discovery at Galley Hill showed that our modern type was in existence in England soon after the glacial period had vanished—a period of several hundred thousands of years Glacial man is much older His lower jaw, with a complete set of teeth, was found four years ago near Heidelberg in a stratum which lay eighty-seven feet from the surface, and was mixed with remains of extinct animals The age of the Heidelberg individual has been assigned to one of the first temperate interludes which broke the *prolonged period of intense cold* in Europe At so early a period—one which makes the age of the Galley Hill man a comparatively recent one —we expected, on the Darwinian theory, to find man in a transition stage, a man-ape or ape-man—a pithecanthropus That conception has dominated the artist when he has sought to reproduce the form of the Glacial European—or, to use a more strict geological term, Pleistocene man A little over two years ago, a graphic reconstruction of the man just then discovered at La Chapelle-aux-Saints appeared in these pages The anthropologist and artist have pictured his mouth, his teeth, his nose—indeed, the whole of the lower part of his face—as very similar to the same parts in the gorilla In representing his attitude, his posture, his feet, legs, arms, and skin, they have drawn largely on the same animal

When, however a *careful study* has been made of his skull, his teeth, and the bones of his body, it becomes very evident that there was very little more of the ape in the Neanderthal type of man than in his modern representative He had certainly, as may be seen from the drawing by Mr Forestier, very striking peculiarities His face was long, wide and heavy, with rather massive jaws but his teeth, as regards their crowns were no bigger or different in shape and size than we see now in many primitive native races The eye-sockets were loose, and the eyes seemed deeply set owing to the great over-hanging beetling forehead, and the nose was wide prominent, large, quite unlike the same organ in negroid races His brain was not small, in most cases it appears to have been above the average of modern Europeans Some of his worked flints show great dexterity His arms and hands were *muscular* roughly molded and strong but used, if one may judge from their shape, much in the same way as we use ours He stood a little over five feet in height There are no features in the bones of the lower limbs to suggest a posture or a manner of walking materially different from those of modern man

His mouth and tongue were larger than ours, and the impressions on the lower jaw for the muscles

The "modern" man of half a million years ago; his skull and his features.

concerned in speech differ so markedly from those seen on the mandibles of modern man that we must conclude that, if speech were present, then it must have been of a primitive nature and different from the vocal articulation of modern man

Most of the remains of the Neanderthal man, like

"The man of from one to two hundred thousand years ago."

According to Mr R. S Lull, an ingenious scientific reconstruction.

those recently found in Jersey, have been unearthed *from the floors of caves*, so that we have no means of judging what period of time may have elapsed since the remains were deposited there. In the case of the Heidelberg man, however, we have some grounds, and from the depth and nature there of the strata some

Declared to be a misconception.

A reconstruction (of two years ago) of the man of La Chapelle-aux-Saints

OUR RUDE FORBEARS

Photographs by courtesy of the *Illustrated London News*.

estimate can be formed of the extreme antiquity of the Neanderthal race. Layer on layer has been laid down by the action of running fresh water, until the deposit in which the Heidelberg man was embedded lay eighty-seven feet below the surface. The rate of deposit we have as yet no accurate means of estimating, but few geologists would assign a period of less than 500,000 years, and most would give a larger figure.

It is becoming thus apparent that not only is modern man of great antiquity, but the earlier stages in the evolution of man have been passed through at a much earlier period of the earth's history than we had formerly any conception of It must be remembered, too, that the Glacial period extended through hundreds of thousands of years; so far as we know, the Neanderthal type persisted throughout the whole of that time in Europe. We must expect, however, to find much individual variation in so vast a period of time; race must have succeeded race, as has ever been the case among living things Presently we shall be able to recognize the older and more primitive from the later and more evolved races of Neanderthal Man

Poisoning by Illuminating Gas

THE French journal *L'Electricien* has been gathering some interesting statistics in regard to cases of poisoning by illuminating gas It appears that for several years past the number of such cases has been rapidly increasing In New York alone there were nearly two thousand cases in one year, many of them fatal The *reason for this* increase is traced to the change in the composition of the gas used for illumination, especially with respect to the amount of carbon-monoxide present Different kinds of gas contain different amounts of this gas, as shown by the following table:

	Percentage of CO.
Coal gas	6 6
Oil gas	10 0
Water gas	40 0

From these figures it is seen that coal gas is the least harmful kind, and that water gas—made by passing steam through red-hot coke—is the most dangerous. For the purpose of saving the cost—or of increasing the profits—manufacturers have from time to time mixed varying proportions of water gas with coal or petroleum gas As the water gas is odorless its presence is not readily detected, and when it is mixed with coal or oil gas a large quantity of the mixture may escape into the air without being noticed In many communities and states the use of water gas is prohibited for this reason

Frost Cartridges

IN the *Monthly Weather Review*, April, 1911, Professor A. G McAdie describes a new device for protecting fruit trees from frost; viz., the "frost cartridge." Just as orchard heaters marked a distinct advance over the old-style open fires, which warmed up all out of doors, so it is believed that these cartridges, which can be used in close proximity to the fruit to be protected, will prove to be more effective and economical than heaters placed on the ground.

The cartridge consists of a cylindrical tube of heavy cardboard or other suitable, slow-burning material, which is filled with a mixture of crude oil, gravel and sawdust. Two stoppers are provided to close the ends of the tube. When filled, the cartridge is suspended by a wire about three feet below the fruit. When used, the stoppers are removed and a torch is applied to small amounts of cotton waste, which have been soaked in kerosene and placed at the ends of the cartridge. A cartridge case two feet long and one and a half inches in diameter will burn about two hours. If the combustion is good there will be nothing left but the gravel and a small residue of charred cardboard

The tubes may be filled during the afternoon hours, although it is found that they will hold the oil without leakage and without softening for several days.

There are two objections to the use of this device in its present stage of development: (1) the danger of fire from the burning ends, and (2) the large amount of solid matter on a portion of which is deposited upon the fruit. Experiments are in progress looking to the atomization of the crude oil so that combustion will be improved.

Stress in Aeroplanes in Curvilinear and Fancy Flight

The Mechanical Significance of Aerial Antics

By A. F. Zahm

Of the many dangers encountered in aeroplaning one of the most clearly defined, as also one of the most seductive, results from fancy flying—from wheeling round sharp horizontal curves, from conic spiraling, from cascading, swooping and undulating in vertical plane curves. The danger is particularly alluring to reckless young aviators engaged in public exhibitions, partly because they do not adequately appreciate the risk, partly because of the intrinsic charm and delight of such varied motion, and largely no doubt because of the liberal applause received from the admiring throng and the reciprocal desire to please that throng, too captivated by the fantastic grace of curvilinear flight, and by the bravery and abandon of the impetuous airman, to realize the hazardous nature of his fascinating maneuvers. Singularly enough the exact magnitude of such hazard, or say more accurately, the increased stress in the machine, though beyond the approximate guess of the practical aviator, is capable of nice computation in terms of the speed and curvature of flight. It seems important therefore to place the computations in ready form before all persons concerned in such maneuvers—the reckless pilot, perhaps with a wife or family dependent upon him, the applauding spectators who encourage his daring, and the cautious manager or company that, for reasons manifold and obvious, wishes to avoid disaster both to the man and to the machine.

During his recent exhibition in Washington, Mr. Glenn H. Curtiss found difficulty in restraining one of his intrepid young aviators from executing various hair-raising maneuvers. The boy loved to frolic in the air like a swallow or bird of prey, to the joy of a light-hearted throng, except possibly his wife and friends. He would plunge from a great elevation to acquire the utmost speed, then suddenly rebound and shoot far aloft. He would undulate about the field like a galloping horse, or an impetuous torrent vaulting over rocks or a rugged bed. He would bank his machine till its wings stood apparently vertical. Mr. Curtiss solemnly warned the aviator and earnestly restrained him, pointing out the danger of sweeping sharp curves at high speed. He then turned to me and expressed the wish that some one would determine exactly the amount of the added stress in curvilinear flight. The following paragraphs embody my response to his wish. With the death of St. Croix Johnstone fresh in the public mind, let us hope that they may be taken to heart by pilots who strive to please the multitude.

When a body pursues a curvilinear path in space the centripetal force urging it at any instant may be expressed by the equation

$$F_n = m\ V^2/R \text{ (absolute units)}$$

$$= \frac{m}{g} V^2/R \text{ (gravitational units)}$$

in which F_n is the centripetal force, m the mass of the body, V its velocity and R the instantaneous radius of curvature of the path pursued by its center of mass. Since the mass may be regarded as constant for any short period, the equation may be verbally expressed by this simple law: the centripetal force varies directly as the square of the velocity of flight and inversely as the instantaneous radius of curvature of the path.

In applying the above equation to compute the stress in an aeroplane of given mass m, we may assume a series of values for V and R, compute the corresponding values for F_n, and tabulate the results for reference. In such manner the following table was obtained. It may be remarked that, on substituting in the equation, V has been taken as so many miles an hour, R as feet, and g as 32 miles an hour, for convenience, this being 32.1 feet per second.

This table shows at a glance the centripetal force acting on an aeroplane, as a fractional part of the gravitational force or weight, of the machine and load. If, for example, the flier is rounding a curve of 400 feet radius, at 60 miles per hour, the centripetal force is 0.55 of the total weight. At the excessively high speed of 100 miles an hour and the extremely short radius of 100 feet the centripetal force would be 4.55 times the weight of the moving mass. The pilot would then feel heavier on his seat than he would sitting still with a man of his own weight on either shoulder. Again for speeds below 40 miles an hour, and radii of curvature above 200 feet, the centripetal force is below one-third of the weight.

Centripetal Force on an Aeroplane for Various Speeds and Curvatures of Flight

Velocity, V, of the Aeroplane	Radius of Curvature, R				
	Ft. 100	Ft. 200.	Ft. 300	Ft. 400	Ft. 500
Miles per Hour	Weight	Weight	Weight	Weight	Weight
30	0.41	0.20	0.14	0.10	0.08
40	0.73	0.36	0.24	0.18	0.15
50	1.14	0.57	0.38	0.28	0.23
60	1.64	0.82	0.55	0.41	0.33
70	2.23	1.11	0.74	0.56	0.45
80	2.91	1.45	0.97	0.73	0.58
90	3.68	1.84	1.23	0.92	0.74
100	4.55	2.27	1.52	1.14	0.91

The entire straining force on the aeroplane in horizontal flight being substantially the resultant of the total weight and the centripetal force, can be found by compounding them. Thus in horizontal wheeling, the resultant force, as seen from Fig. 4 (page 196) is approximately

$$F = \sqrt{F_n^2 + W^2}$$

In swooping, or undulating in a vertical plane, the resultant force at the bottom of the curve has its maximum value

$$F = F_n + W$$

and at any other part of the vertical path it has a more complex, though smaller, value which need not engage us here.

It is obvious from the foregoing discussion that the greatest stress in the machine occurs at the bottom of a swoop if the machine be made to rebound on a sharp curve. The total force $F_n + W$ sustained at this point may be found from the table if V and R be known, by adding unity to the figures given, then multiplying by the weight of the machine. For example, if the speed should be 90 miles an hour and the radius of curvature 200 feet the total force on the sustaining surfaces would be 2.84 times the total weight of the machine. In this case the stress in all parts of the framing would be 2.84 times its value in level flight, when only the weight has to be sustained. The pilot would feel nearly three times his usual weight. We may conclude from the foregoing investigation that in ordinary banking at moderate speeds on moderate curves, the additional stress due to centripetal force is usually well below that due to the weight of the machine, and that in violent flying the added stress may considerably exceed that due to the weight of the machine, and may be dangerous, unless the aeroplane be constructed with a specially high factor of safety. But there is nothing in the results here obtained that seems to make sharp curving and swooping prohibitive, for if the framing of the machine be given an extra factor of safety, at the expense may be of endurance and speed, it may be made practically unbreakable by such maneuvers and still afford to the operator and spectators alike all the pleasures of

(continued on page 196)

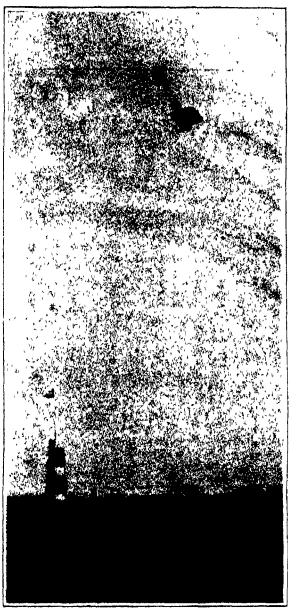


Fig. 1.—A "staircase" drop that strains a machine to the danger point when the path is straightened out in alighting.

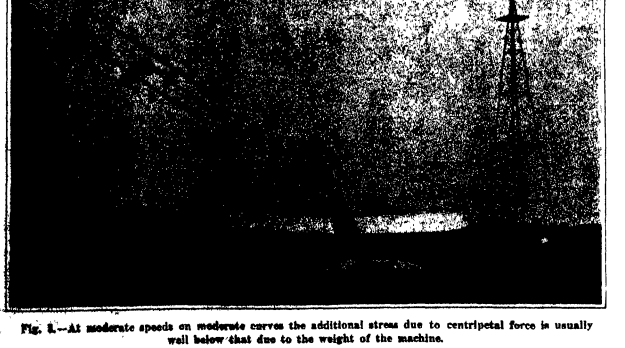

Fig. 3.—At moderate speeds on moderate curves the additional stress due to centripetal force is usually well below that due to the weight of the machine.

Magic Effects on the Stage and Off

What the Mirror Does to You

By Alfred J. Lotka

IN the issue of December 24th, 1910, of SCIENTIFIC AMERICAN Mr. Herring propounded the problem, "Why does a mirror reverse right and left, but not up and down?" In an answer by Mr Keen (January 28th, 1911) it was rightly pointed out that the cause of this inversion of printed or written characters (the example cited by Mr Herring) lies in the manner of presenting the same to the mirror It is the observer who turns the sheet about, and not the mirror

Now at first sight it may appear that this explanation completely settles the whole question, and that the image in the mirror is indeed a true and exact copy of the original In point of fact this is not in general the case, although it is in a sense true of an object having only two dimensions, such as the plane surface of a sheet of paper, and the writing upon it For this reason, in order to obtain a full understanding of what the mirror does, it is necessary to choose another object for our example, one which extends in the three dimensions of space

Let us take first of all a simple case, which for our immediate purpose may be still two-dimensional, provided it does not lie in a plane parallel to that of the mirror Suppose we present to the mirror a V-shaped object *CDE*, for example, a wire bent to the shape indicated (Figs 1 and 2) To an observer in front of the mirror, the image of *CDE* will appear located at *C' D' E'*, as shown in perspective in Fig 1 and in plan in Fig 2 Note that the point *D* which lies farthest back in the original object, in the image is represented by the point *D'* lying farthest forward Note also that *C' D' E'* may be produced from *CDE* by turning the latter *inside out*, and displacing it a certain distance backward If this is not immediately obvious, imagine *CDE* to be made of flexible material, such as string If the point *D* is held fast, and *C* and *E* are pulled forward through a certain distance, evidently a figure like *C' D' E'* is obtained We may therefore say that what the mirror does to *CDE* is to *turn it inside out*

Now, so long as the object is merely two-dimensional, as in the present example, there is little gained by this point of view For we might with equal justice say that *CDE* has simply been rotated about *AB* through 180 degrees

The matter assumes a very different aspect as soon as we turn to a three-dimensional example Suppose a glove is lying on a table in front of the mirror *AB*, as indicated in our second illustration (Figs 3 and 4) What will its image be? Suppose the glove was that which fits your right hand, the image will be such a glove as you would obtain by turning your right hand glove inside out—a left glove Figs 3 and 4 illustrate this case If you are not convinced, try it Suppose a one-legged man could be put through the operation which the mirror performs upon you Should he have had the ill luck to take off his shoe before he underwent the change so that the shoe retained its original character, he would now find that it no longer fitted his only foot! For if this was his right originally, it is now his left, and his shoe no longer fits it (Fig 5). He might of course easily avoid this awkward predicament by wearing his shoes while being "turned inside out," in which case his shoe also would be converted into a left shoe. The perfectly symmetrical man would not be affected in any way, as regards

(Continued on page 197.)

What the mirror does to a solid body is to turn its surface inside out.

Conjurer's trick box for "Vanishing Lady" performance.

A New "Vanishing Trick" Box

A FAVORITE trick both with the professional conjurer and the amateur is to cause the unaccountable appearance seemingly from nowhere of various objects or persons, and their equally mysterious disappearance. Various artifices and devices have been used, according to circumstances, to produce these enigmatic effects. Our illustration shows a new form of trick box, by the aid of which the conjurer may for example exhibit the remarkable manifestation of "the vanishing lady." The mechanism of the device is very simple. The box is provided with a drawer, which slides out backward, in the direction away from the audience, so that when withdrawn it is hidden from view, its front panel then forming the back wall of the box as seen by the audience, when the flaps in the sides of the box are opened for inspection. The conjurer starts by opening the lid at the top of the box. A system of cords (*IF*) and pulleys is so arranged that this action of lifting the cover at the same time causes the drawer, containing the vanishing lady, to retreat backward into the position shown in the body of the illustration. The cords may be made black, so that to the audience they are invisible The flaps are opened, exposing the apparently empty box to view To fully convince the audience, a rod may be passed through the box, showing that there is no deception. The flaps are then closed and the lid brought down The conjurer makes a few passes over the box, addresses his audience with the usual kind of patter, and presently opens the box once more, this time tilting it forward, so that the audience can look right into it from the open lid. And there, right enough, appears the mysterious lady in the box. For on closing the lid the drawer has moved forward into the box under the action of springs In making his passes the conjurer has loosened two catches, with the result that, on opening the lid for the second time, only the central portion *C* of the cover is raised, leaving behind (unknown to the audience) a narrow marginal frame (shown at *B* in the detail drawing) It is this frame to which are attached the cords actuating the sliding drawer. Hence on lifting only the main portion of the lid, without its marginal frame, the drawer is left within the box, and is exposed to view, with its contents, on tilting the box forward. There is, of course, now no difficulty in once more closing the chest, fastening the catches, and displaying once more an empty box upon opening the lid Variations and embellishments can of course be added to this performance to increase the spectacular effect But it may be left to the ingenuity of the reader to devise these for himself.

The apparatus here described was designed by Mr. R. B. Smith, an Australian inventor now resident in New York, and the accompanying drawing was prepared by the artist of the SCIENTIFIC AMERICAN from a small working model kindly lent by the inventor. Mr. Smith is identified with numerous inventions chiefly relating to clocks and illusion apparatus for theatrical use.

HANDY MAN'S WORKSHOP

[The Editor of Handy Man's Workshop will be glad to receive any suggestions for this department and will pay for them, promptly, if available.]

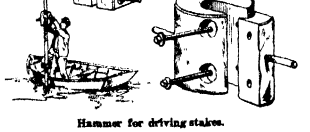
Some Methods of Inserting Small Screws

IN Handy Man's Workshop of May 27th we described a simple device for holding small screws, while inserting them into the work with a screw-driver. A number of other suggestions for doing this work have since been received and are given below

Here are three good ways for holding small screws, of either machine or wood type. A small piece of wire is bent double at one end, and slipped under the head of the screw. This serves to hold the screw steady, while the screw-driver is manipulated After the screw has a firm hold, the wire is removed A second way is to cut a small strip of tin to the shape shown in the accompanying sketch. This is a universal

Device for holding small screws.

tool, as it holds screws of different sizes A third way is to take a strip of rather stiff paper and push the screw through it at one end When the screw holds, the paper is torn away.—B F DARNELL

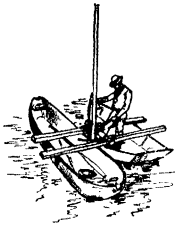


The following is a scheme that the writer has used for twenty years. Take a soft piece of wood and trim it to fit tightly into the slot in the head of the screw Press the tapered point of this wooden screw-driver into the slot, then insert the screw, screw it into the hole, and finally turn it home with a metal screw-driver With this device, one can set a screw in the back of a spring clock, or other piece of machinery, where it is impossible to reach the spot with the hand, or with the tool illustrated in the issue of May 27th.—W R. CRAWFORD

To insert small iron or steel screws, a very simple and handy way is to rub the end of a small screw-driver over one pole of a horseshoe magnet The end of the screw-driver will be readily magnetized, and will pick up and hold the small screws so that they can be inserted. Many of the small screws in clock and watch works are so tiny that a separate tool cannot be readily used without danger of dropping them into the movement.—JAMES E NOBLE

Methods of Driving and Pulling Stakes

By Albert F. Bishop



A GOOD hammer for driving mooring stakes may be made of an elm butt, nine or ten inches in diameter, and fourteen inches long. In the center a hole should be made, three inches in diameter It can be sawed on a band saw by removing the saw

Hammer for driving stakes.

guide This done, two parallel cuts should be made, three inches apart from the periphery to the hole, leaving a block which can afterward be replaced and secured to the body of the hammer by means of two five-inch bolts, as shown in the drawing When tightly bolted, the result will be equivalent to a solid ring-shaped hammer. This should weigh about 35 pounds Handles may be driven in at opposite sides of the hammer so as to permit of operating it readily In use the block is unbolted and the hammer is placed on the stake, after which the block is replaced and bolted in place again. A collar is attached to the stake upon which the blows are struck. The collar may be made of curly hickory, or wood that will not split, after the pattern illustrated, with ¾-inch bolts used for clamping it to the stake The operation of the device is shown quite clearly in the drawing, and in order to prevent the collar from slipping, it would be advisable to use spurs on the V-shaped portions of the clamps, so that they will nip into the stake

In pulling stakes the lever is commonly used, although a Spanish windlass can be operated by one person, and is very sure to perform the work satisfactorily. The windlass may be made of a round piece of hard wood about four inches in diameter, with holes bored near each end to receive the iron bars or levers with which it is turned It should be rested on a couple of half boxes hollowed out to fit the four-inch barrel. These journal boxes should be greased and should be secured to pieces of scantling laid across two boats. To grasp the stake, a chain is

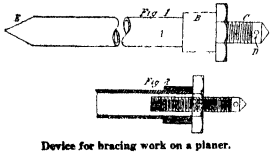
Raising a stake with a windlass.

The chain grip.

used This should have a ring or hoop in one end The chain is passed around the stake and slipped through the hoop, and then is given three turns about the windlass. When the chain is under tension it will grip sufficiently to raise the stake without slipping. When lowering the chain for a fresh grip on the stake, it will slide down easily if shaken slightly by the handles

Handy Fly Killer

MY "Handy Man" made me such a fine "typhoid fly" killer, that I would like the wives of other "Handy Men" to have it When renewing a window screen, there was a small piece of the wire screen left over; my husband took a piece about 4 inches wide



Fly killer made of wire netting.

and 12 inches long, doubled it, fastened the ends in a saw kerf, sawed in the end of a small stick about 14 inches long This gave me a "weapon," with which I can easily kill intruding flies by a sharp quick stroke; it is very effectual, indeed.—EDITH BADER

A Planer Brace

AN excellent device for bracing work on a planer or boring mill is pictured herewith

Fig. 1 shows the tool and the way it is assembled The part marked *A* is a piece of 1¼-inch pipe flattened at *B*. *B* is a nut which fits over the pipe *A*. *C* is a

Device for bracing work on a planer.

piece of 1-inch round steel threaded and drilled at *D* for the purpose of adjusting its length By having an assortment of lengths of pipe as shown at *A*, the nut *B* and rod *C* remain together and may be inserted into the pipe end at will.

Fig. 2 shows a sectional view

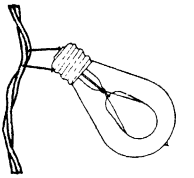
How to Prevent Taps from Breaking

THE sketch reproduced herewith shows a handy kink in the way of preventing taps from breaking It is very discouraging to try to tap out a small hole in a piece of work and have the tap break off in the hole. In most cases this means that you must have the broken part of the tap annealed before it can be drilled out To avoid this difficulty cut a line parallel with the shank of the tap as shown in the drawing The tap is then heated, half way between the threads and shank end, to a light blue color This

A tap that gives warning of undue strain.

will eliminate the breaking of the tap, as the shank will twist before it will break and the line will show that the shank of the tap is twisting, thus giving the user warning

This has proved to be a very valuable little kink on small taps



Locating a Break in an Electric Flatiron Cord

By Paul H. Woodruff

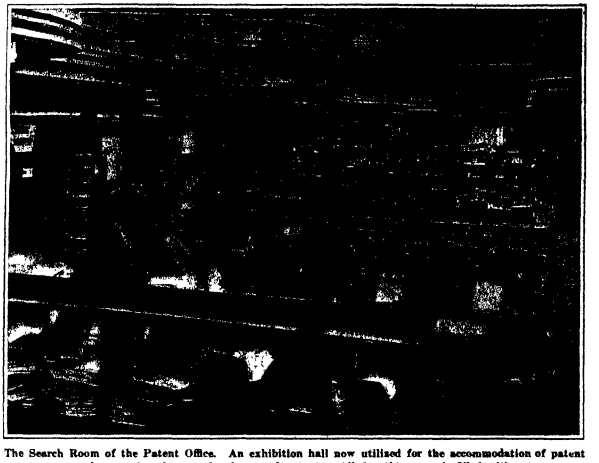
ELECTRIC cord of the kind furnished for connecting an electric flatiron with the supply, by way of a plug inserted in a lamp socket, is usually heavily insulated with a thick covering of rubber and a sleeve of coarse woven cotton For this reason it is rather difficult, when the conductor becomes broken inside its covering, to locate the exact point of the break, because since the insulation is much stiffer than the stranded copper conductor itself the ordinary bending test will not show the injury with any degree of certainty

As an example, a household electric flatiron recently "went dead," and an examination showed that the heating elements and the terminals of the iron were all right To all outward appearances and tests the cord was all right, too, but a lamp connected by a pair of short wires to its apparatus end failed to light up As it was inexpedient to obtain a new cord at once, and the implement was needed immediately, the following simple test was resorted to

The plug on the end of the cord being screwed into the supply socket, with the socket key turned to "off," two common brass pins were inserted into the double cord, one into each conductor The pins were so placed that their points pierced the cotton and rubber

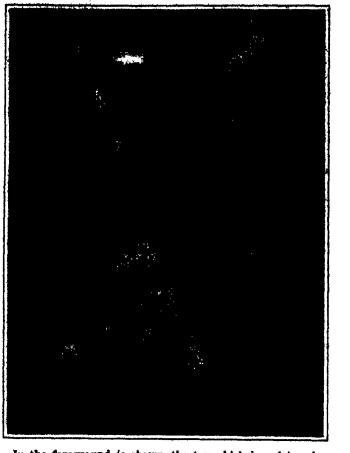
Locating a break with lamp and pins.

insulation and made contact with the stranded copper conductor within The key switch was then turned on and an ordinary sixteen candle-power incandescent lamp, held in the hand, was pressed against the heads of the two pins in such a manner that one pin made contact with the metal sleeve of the lamp base, the other with the metal button in the center of the base The lamp immediately lighted up, showing that the cord was intact from the plug to the point where the pins were inserted



The current being turned off again, the pins were withdrawn, and replaced at a lower point in the cord—that is, nearer the apparatus end—and the lamp was pressed against them This process was repeated at intervals of a few inches until a spot was found, within a few inches of the flatiron end, where the lamp did not light up. The pins were then moved back and forth until the exact spot was found where the current ceased to flow The cord was then cut off at this point and one of its conductors found to be broken cleanly in two It was an easy matter to strip the insulation from the newly cut ends and reinsert them in the flatiron connector plug, when the iron was found to be as good as ever

This is an extremely simple "kink," but, like many other simple things might not occur to everyone who finds himself in the same predicament The most important precaution to observe is to turn the current off before inserting or removing the pins A shock in the fingers is not serious, but it is a trifle unpleasant, especially with alternating current at 110 volts



Soldering Flux.—A good soldering flux for copper is a heavy paste of resin This paste is made by dissolving as much resin in benzine as the benzine will take up The paste is easily applied with a stiff brush.—H. D CHAPMAN

The Inventor's Department

Simple Patent Law; Patent Office News; Inventions New and Interesting

The Search Room of the Patent Office. An exhibition hall now utilized for the accommodation of patent attorneys, who examine the records of granted patents. All day this room is filled with attorneys and their assistants, who sometimes appear in such great numbers that they are forced to use the halls and other rooms for their work.

In the foreground is shown the tar which has dripped from the model-vault lights, to protect the boxes from which old carpets and tarpaulins have been spread.

The Need for a New Patent Office

The Overcrowded Conditions in an Obsolete Type of Building

THERE is one thing which the inventors of this country have not yet obtained and which they have a right to demand, and that is a new building for the United States Patent Office.

When it is stated that the inventors have the right to demand it, that is exactly what is meant, in spite of the fact that the small army of examiners and clerks who work day in and day out within the walls of the old Patent Office, in cramped and out-of-date surroundings, would be affected most materially and directly by the erection of a new and commodious building. The discomforts that these latter must bear, and the very obvious disadvantages under which they labor, are not nearly so far reaching or important as the fact that poor facilities for work retard work, and the fact that employees are laboring under conditions which ought not to exist and which would scarcely be tolerated in a well-ordered and up-to-date factory, leaves the inventor, who is the sole customer of the Patent Office, in the position of not having his work done with the dispatch and expeditude which he should expect from his dealings with the Government, and which might obtain were the force of workers not herded together in an old-fashioned and overcrowded building.

This statement may come as something of a surprise to the readers of this article. Most of the inventors have seen a picture of the Patent Office. That is to say, they have seen pictures of its outside. There is no intention to belittle the classic outlines and graceful proportions of the Patent Office structure, which as an architectural achievement leaves nothing to be desired. It is a handsome and solid building of white stone, and has the appearance of an old Greek temple, or if one does not care for romantic comparisons it may be likened to the appearance of an art gallery or a museum.

But there are about one thousand people inside of this beautiful building who have something else to do besides contemplating its architectural grandeur. It is not surprising that some of them should wish for modern conveniences in place of classic excellence. A quarter of a century ago the working force of the Patent Office occupied but a small part of the building. Various Secretaries of the Interior have, however, from time to time, managed to get rid of the Land Office and the Indian Office and some other bureaus of Uncle Sam's largest department, and they have been housed elsewhere. At the present time only the personal staff of the Secretary of the Interior shares the building with the Patent Office. Secretary Ballinger, indeed, offered to move out of the quarters he occupied, if by so doing he could relieve the growing need of the Patent Office for more space. The few rooms, however, that the Secretary's force could relinquish would not permanently benefit the Patent Office. To tell the truth, it has outgrown its present quarters, and a new building has become a crying need.

One has only to enter the Patent Office and look about him to realize the weight of this statement. Like a boy who has long since outgrown his Sunday suit, but who is required by parental authority to continue to wear it, the Patent Office goes on expanding without room for expansion. The boy's arms hang far below the sleeves of his jacket, and his legs look ridiculously attenuated in the short, tight pants. It is unfair to the boy to make him the laughing stock of his companions. It is equally unfair to build costly modern buildings at public expense for other branches of the Government, and let the Patent Office, which is one of the few bureaus of the Government that is absolutely self-supporting, and which has an actual surplus of nearly seven millions of dollars, all of which has been paid in by the inventors of the country, go on occupying its old quarters, which, like the boy's suit, have bulged at the seams these many years.

Take, for example, the matter of the storage of records. Can anyone be so insensible to the value of the records of the inventions of the last century to claim that their careful preservation is not a matter of the gravest importance? Every conceivable inch of space in the Patent Office is now being used for the storage of valuable records, which if they should ever be destroyed, could never be replaced. The hallways are used for the shelving containing the copies of granted patents. These copies are being constantly called for, and must be kept right at hand, where they can be easily found at a moment's notice. Yet their orderly arrangement is impossible, when they must be put wherever there is available space. There are now over a million of patents which have been granted, and the office must keep on hand a sufficient supply of copies of these to satisfy daily and hourly demands for them.

Room must also be had for the convenient and safe filing of the original papers in each one of these patent cases. The drawings, too, must be carefully preserved, for together they constitute an actual, visible record of the achievements of the American people in the field of invention since the establishment of the patent system. Where in all of the different branches of the Government is there a more valuable collection of papers, or a more authentic and significant record of the progress man has made in the last one hundred years?

The Scientific Library of the Patent Office, with its priceless collection of publications on the subject of inventions, including copies of two million foreign patents, occupies a small section of a corridor, and the books are inconveniently disposed in a very restricted portion of the galleries which were originally intended for the display of models. The value of the library is almost beyond estimate, as many of the publications in the collection could not be replaced. In the old-fashioned building, which is not fire-proof or modern, they are exposed constantly to the danger of destruction by fire. The warning furnished by two previous fires of a disastrous nature in the Patent Office, has passed unheeded. The Assignment Division, which is one of the largest in the Office, occupies a corridor, also intended at one time for the model exhibit. In it are kept the records of the titles to inventions. The deeds showing these titles are as important, if not more so, as any collection of deeds to real property, and their destruction would be a calamity so far reaching as to touch the rights of nearly all the leading manufacturers and merchants of the United States. In this division the desks of the clerks are packed closely together, none of the clerks get the number of cubic feet of air prescribed by the rules of hygiene, and some of them work all day under artificial light. The galleries are filled with the copies of patents, which now overrun the entire building.

Many of the examining divisions occupy cramped and badly lighted rooms. Each division is forced to keep its own files of pending applications, and from five to eight persons are the rule in each room, and more are frequently found. Even the basement of the building has been partially remodeled, so that some of the store rooms could be utilized for the use of the working force.

When it is remembered that dust, rats, and mice, to say nothing of possible conflagrations, create irreparable damages in a comparatively short time, the proper housing of the Patent Office becomes a

question of national interest. Every inventor and manufacturer of the nation may be said to suffer from the danger that would arise from the destruction of some important paper, the bearing of which on a future invention might be of the utmost importance.

The same is true of the Patent Office models. Upon an improper understanding of the matter, Congress has during the last few years made many attempts to dispose of these models by sale, gift, or otherwise. When they were crowded out of the Patent Office, they were placed on exhibition in a building adjacent to the Office in expensive glass cases, so that they might not only be accessible as a part of the official records in frequent use by the Office and for use as evidence in suits in the United States courts, but that they might also furnish a very interesting and instructive exhibit to the general public. It was customary for excursions from colleges and schools to visit Washington mainly for the purpose of studying this exhibition of historical objects, which showed the development of the mechanical arts

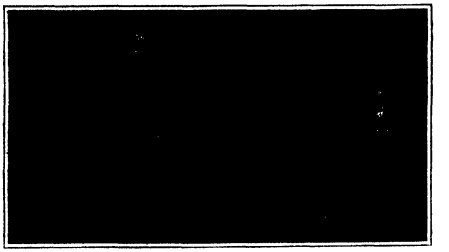
Subsequently Congress omitted to appropriate money for the rental of these exhibition halls, and the models were placed in storage. The cases were sold and the models nailed up in wooden boxes, labeled, and given over to perfect oblivion, so far as the public is concerned.

Eventually Congress was convinced that it would be a mistake to dispose of these models, owing to the fact that they are still used in the courts as evidence in important cases, where vast sums of money have been saved in litigation on account of the irrefutable testimony given by these inanimate but eloquent witnesses

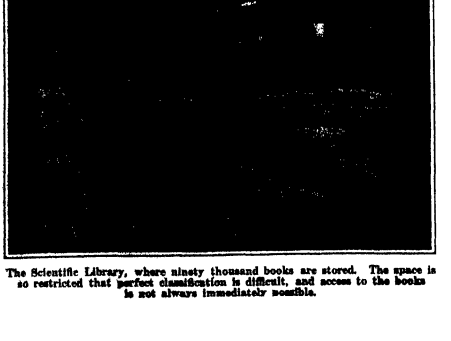
The high state of perfection reached by mechanical drawing now renders the construction of a model to accompany applications for patent unnecessary Previously to the early '80's the drawings submitted did not always disclose clearly the real invention, owing to poor mechanical drawing, and models were absolutely essential. It is evident, therefore, that the present collection of models is the only real proof, actual and existing, of numerous inventions, and each and every one is liable to be called for and relied upon as evidence in the courts to-day

The framers of the Constitution of the United States recognized particularly the necessity for encouraging the development of two faculties of the human mind in order that the young republic might speedily take her place in the front rank of the nations of the world. These faculties, thus recognized and encouraged, were those of literature and invention. Accordingly there was embodied in the Constitution that provision that Congress should have the power to promote the progress of science and the useful arts, by securing for limited times, to authors and inventors, the exclusive right to their respective writings and discoveries. Under this wise provison the present patent and copyright laws have been enacted by Congress.

The Library of Congress, one of the world's most beautiful structures, is proof enough that the artists of the nation, the authors, the musicians, have not knocked in vain at the door of Congress that their works might be preserved to posterity forever. The new National Museum too provides ample room for the display and preservation of records of the past, pertaining to archeology, zoology, anthropology, geology, and history. The implements of war and peace presumably used by prehistoric races are spread out before the public and are available for research by the student. The whole history of man may be studied and contemplated by whosoever will.



On the other hand, the Patent Office models, the actual embodiments of the first inventions of our many arts and sciences, are allowed to lie—more than one hundred and fifty thousand in number—stored in wooden boxes in the cellar of the office building of the House of Representatives. Not that they are wanted



Portion of the corridor, 20 by 40 feet, in which twenty-two persons operate typewriters; the ceiling is 8 feet 3 inches from the floor.

Storage place for copies of patents in space originally intended as an exhibition hall for Patent Office models. All the available room in the halls of the building is thus occupied by copies of patents.

In this room in the Patent Office, divided by a temporary partition, twenty-four persons work all day under artificial light. The windows look into the north portico and no sunlight ever comes into the room.

The Scientific Library, where ninety thousand books are stored. The space is so restricted that perfect classification is difficult, and access to the books is not always immediately possible.

there! But Congress would not appropriate money for their proper keeping, and there is no longer any room for them in the old Patent Office building They had to be sheltered somewhere, and a few vaults happened to be empty in the new House office building, so consent was given to store them there

The mere fact that models are not longer required by law to be filed by the inventor with his application for patent, does not render those that have been so offered and accepted in the past any less valuable as records and evidence In fact, their value as exhibiting what has been done in the past in nearly all known arts increases rather than diminishes as time goes on

When the Patent Laws were revised in 1870, the following provision was inserted in the Revised Statutes

"484. The Commissioner of Patents shall cause to be classified and arranged in suitable cases, in the rooms and galleries provided for that purpose, the models, specimens of composition, fabrics, manufactures, works of art, and designs, which have been or shall be deposited in the Patent Office, and the rooms and galleries shall be kept open during suitable hours for public inspection."

In spite of this mandate of the law, inventors and manufacturers, visitors and tourists now inquire in vain at the Patent Office for the rooms where the models are displayed They are surprised to hear that they are stored in almost inaccessible cellars

It is difficult to reconcile this history of the Patent Office models with the beneficent government which provides palatial buildings for nearly every branch of the service, and erects stately museums and libraries. This anomaly could easily be overcome by the erection of a new and suitable building for the Patent Office, and it should speedily become the business of every citizen—for every citizen benefits by the patent system of the United States—to advocate the construction of such a building

As pointed out in the early part of this article, the Patent Office has an absolutely net surplus in the United States Treasury of nearly seven millions of dollars Every dollar of this has been paid in by the inventors of the country The sum is more than sufficient to build an adequate and modern building for the Patent Office. Congress has only to give the necessary authority, it does not have to appropriate a single dollar out of the revenues of the Government The money is there, the Patent Office has earned it, the inventors have paid it in There ought to be a building wherein the records of inventions could be safely and conveniently kept, beyond all danger of destruction There ought to be well-lighted and properly ventilated accommodations for the examiners and clerks who perform the difficult and important work of determining whether an invention is new or old Moreover, inventors have the right to demand that the facilities be furnished whereby their applications for patent can receive the highest possible degree of care and accuracy in examination

It is not likely that this neglect on the part of Congress to provide for the Patent Office has been deliberate, but it arises from the fact that most of the members of Congress are not in possession of the facts regarding the needs of the Office What is required now is a campaign of publicity, a campaign whereby not only Congress, but the people everywhere, may realize that the inventors of the nation are paying for something to which they are justly entitled in the Constitution, but which they do not always get

Without great commercial resources and activity a nation cannot become great The inventors and the manufacturers, the buyers and the sellers furnish the sinews of the country, and upon invention and invention alone has commerce been founded. Invention, instead of lessening the number of distinctive kinds of employment, has been shown by actual experience to have increased them

The late Senator Daniel of Virginia, who was an enthusiastic worker for the inventors, is the author of a bill which expired with the last Congress, but which provided for and specified the particular location upon which the Greater Patent Office should stand. This site is immediately north of the Library of Congress, facing the east front of the Capitol

It is inevitable that this site must ultimately be occupied by a Government building, and since the Patent Office is the twin sister of the Library of Congress, considering its protection of the products of the human brain, there is no doubt that it should be so located. The present Commissioner of Patents has repeatedly urged in his reports, and orally, to Congress the necessity for improved and modern quarters for carrying on the work of this important bureau Every month that passes deepens the gravity of the present situation, and since it will take years to erect such a building as will be required, the action should be taken by Congress at the earliest possible moment

Notes for Inventors

Liming Apparatus Needed.—In many localities the soil is limed at intervals and it is very common to see piles of lime spaced apart throughout the fields The former practice in liming the soil was to apply large amounts (1 to 3 tons per acre) at long intervals. Investigation has shown, however, that, as a rule, it is better practice to apply smaller amounts (500 to 1,000 pounds per acre) at shorter intervals One difficulty in the way of a general adoption of the latter practice has been the lack of an implement that will evenly distribute such small applications of lime It ought not to be difficult to devise such a distributing machine, and there is no doubt that an efficient implement for this purpose would aid greatly in promoting a desirable agricultural practice.

A New Form of Package.—The wrapping of merchandise, particularly proprietary articles, whether they be medicines or breakfast foods, has received much thought and great advances have been made. There appears, however, to be a field for improvement in a wrapper which will serve its purpose as a distinctive, attractive label for the package until it has been sold at retail to the consumer and can then be utilized to wrap the package for the customer in the usual way This might be effected in various ways, such, for instance, as by breaking a seal on the label wrapper and reversing the latter to bring its plain side into position to form the outer cover of the package Such a wrapper should be popular with the retailer, the field of usefulness is practically unlimited and a satisfactory solution of the problem will doubtless require the careful consideration of an ingenious inventor.

Fishing by Machine.—Just think of a man out fishing and wanting mechanical help in catching the fish! This is provided by Wladyslaw Filipowski of Hawthorne, Ill., in a patent, No 999,214, for a fishing device which may be screwed into a post, pile or other support and has a spring arm over which the line is guided and a trigger to which the line is connected so that tension on the line, as when a fish bites, will pull the trigger and release the spring arm so it can pull upon the line

New Baseballs Two baseball patents, Nos. 999,526 and 999,527, have been secured by Benjamin F. Shibe of Bala, Pa One of the patents shows a ball with a rigid, inflexible central core and layers of thread wound upon it and the other a layer of highly resilient material between the inflexible core and the layers of thread In the description accompanying patent No 999,526 the patentee states that heretofore baseballs have been constructed with the dilapentous windings on a central core or foundation of a resilient, yielding substance such as rubber, upon the theory that the "rebound ancy" of the structure was derived from the action of the resilient quality of the central core, but he has found that the use of a resilient core is unnecessary to produce resiliency in the ball, but that by the use of a rigid, unyielding and inflexible center core the reaction of the resilient qualities of the windings from a blow is more prompt and of greater effect and that the ball responds or rebounds with greater resiliency from the bat than if the core were more resilient and less resistant. When it is considered that probably more than twenty-five thousand baseballs are made every working day in the year, the importance of improvements in this line becomes evident.

A Bow Separator for Motor Cars.—The Packard Motor Car Company is the assignee of a patent, No 994,852, for a bow separator for vehicle tops, invented by Allen Loomis of Detroit. The separator is especially for use on automobiles, and the machine has a rest on which is supported the lower long bow of the top when the top is lowered The separator is to hold the bows apart so they will not rub against one another Thus the separator is supported on the lower long bow and it has recesses which receive the intermediate bows, and also supports the upper long bow. Thus all the bows can be secured together and be supported on the vehicle and the weight of the top bow will not be exerted on the intermediate bows and the bows will not rub against one another.

Melting of Snow.—Samuel Friedman of New York city has patented No. 999,445, a snow melting machine, and a method of converting snow into slush, the latter consisting in imparting heat to the snow and also adding salt to prevent the formation of caked masses of snow The machine has a tank and a chute through which the snow is conveyed to the tank, and a spring-supported plow, which can yield to pass obstructions

Legal Notes

Classification of German Patents.—The United States Patent Office has for sale a translation of the Manual of Classification of the German Patent Office This translation and the numerical list of German patents, classified according to classes, sub-classes and groups, accessible in the Scientific Library of the United States Patent Office, will greatly facilitate the searches in the German patents.

Applying to a Court for a Patent.—In sustaining a demurrer and dismissing the bill in the case of Westinghouse Electric & Manufacturing Company v Ohio Brass Company, 169, O G page 284, the United States Circuit Court for the District of New Jersey held that the remedy by bill in equity to obtain a patent which has been refused by the Patent Office, is a part of the application for patent and the failure of the complainants to institute proceedings within one year after the last official action on their application, to wit, the adverse decision of the Court of Appeals of the District of Columbia, is a bar to such proceedings by bill in equity.

Ex Parte Harris.—In affirming the decision of the Commissioner of Patents, in the case of ex parte Harris, the Court of Appeals of the District of Columbia has decided that claims, for a method of preparing beverages, which include the three steps of preparing, storing and dispensing the beverages, cover mere aggregations, since each of these steps is complete in itself and independent of the others The method involved was for preparing beverages such as tea or coffee, in which a current of boiling liquid was admitted within a charge of material, the resulting infusion was heated to a steaming condition, and the infusion so produced was stored under the pressure of the steam evolved therefrom and free from contact with the charge.

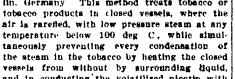
RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

BARRETTE.—A. SCHAER, New York, N. Y. The objects of this invention are to provide a barrette which, when once placed in the hair, will be securely locked in position by gripping the strands of hair, and thus keeping the stray locks in place, and avoiding danger of displacement or loss; to provide a barrette which will be simple of construction, ornamental and readily attached and detached.

Of Interest to Farmers.

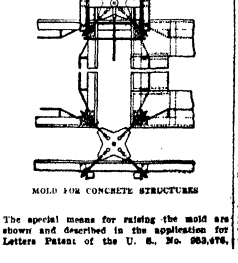


INCUBATOR.—G. H. LEE, Omaha, Neb. Among the principal objects the invention has in view are: To provide means for ventilating an incubator wherein the ventilation is diffused, preventing the formation of drafts and avoiding the necessity of forcing air through the machine, and to provide a simple, efficient and durable construction whereby the ventilation may be varied.

THRESHING MACHINE.—C. M. FRICK, Township 23, Pawnee County, Kan. This invention provides a feeding conveyer which may be thrown in one position so as to feed the material to the threshing part of the machine, or may be shifted to another position, in which it feeds the material over the end of the machine onto the ground. Another feature is a screen for sifting grain from chaff, which will be automatically maintained in a substantially horizontal position irrespective of whether the machine is going up or down hill

Of General Interest.

METHOD OF REMOVING NICOTIN FROM TOBACCO.—J. SARTIG, Nikolassee, near Berlin, Germany This method treats tobacco or tobacco products in closed vessels, where the air is rarefied, with low pressure steam at any temperature below 100 deg. C., while simultaneously preventing every condensation of the steam in the tobacco by heating the closed vessels from without by surrounding liquid, and in condensing the volatilized nicotin with the steam carrying it away to devices of any known construction for recovering the nicotin



FOUNTAIN PEN.—W. A. HOUSTON, Tracy Pen Co., Tracy, Minn This device insures a uniform flow of ink to the pen nibs and paper, and its simple construction affords means for preventing the dropping of ink from the feeder or pen point to the paper in case the ink is fed too freely at times,

FOUNTAIN PEN

whereby the surplus ink supplied is effectively taken up and retained until required, the writing rendered uniform and regular, and blotting, caused by the dropping of ink from the pen point, is avoided The overflow reservoir is so constructed that a relatively large amount of surplus ink may be confined within a small space at the end of the feeding device The device illustrated herewith is a sectional view taken axially through the nozzle portion of the pen provided with the feeding device, and showing part of the end of the ink reservoir

MOLD FOR CONCRETE STRUCTURES.—J. S. LINTON, 1530 South Central Park Avenue, Chicago, Ill The illustration in this case shows a mold or form for making concrete structures, such as walls, columns, beams, etc., and arranged to securely hold the mold parts in position, to allow of raising the mold as the building of the structure progresses, and to temporarily support the concrete material to be used in the formation of the structure

MOLD FOR CONCRETE STRUCTURES

The special means for raising the mold are shown and described in the application for Letters Patent of the U. S., No. 983,476, granted to Mr. Linton. The mold is provided with sets of uprights having brackets for supporting horizontal beams extending from one set of uprights to the other and in which the mold sides are secured so that the concrete material can be readily filled into the space between the opposite mold sides.

Hardware and Tools.

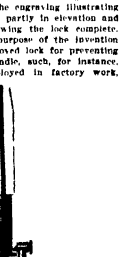
RAZOR STROPPING DEVICE.—MILLARD F. COONS, 414 Broadway, New York, N. Y The invention has for its purpose the provision of a device with two arms articulated together, one of the arms being pivoted to the frame in which the stropping member is secured, a razor blade being mounted on the other arm The perspective view of this durable strop shown in the engraving represents the device in use. While it is not necessary to be used a honing strop can be readily applied to

RAZOR STROPPING DEVICE

the device The device is simple in construction and easily operated when placed in the palm of the hand The blades can be sharpened with great rapidity, and an easy free and clean swing of the blades may be obtained against the strop member The complete outfit weighs three ounces This improvement is Patent No. 1,000,237, issued August 8, 1911, and is to be commercially known as the "Millard Simplicity Stropper."

Heating and Lighting.

FURNACE.—W. SCHEWELER, Gulfport, Miss. In this patent the invention has reference to furnaces for melting lead, and for other purposes, and has reference more particularly to a furnace in which is provided a movable support for a crucible or the like, together with means for moving the support into and out of the furnace



Household Utilities.

KITCHENETTE STOVE.—E. S. ALLEN, New York, N. Y The inventor mounts a kitchenette stove upon journals or bearings and provides it with gas from a gas pipe section, this gas pipe section being provided with a valve fitting into a stationary fixture to which gas is supplied, the arrangement being such that when the stove is tilted into either of its two positions the gas is turned on or off by the action of the valve

Machines and Mechanical Devices.

ADDING MACHINE.—C. B. CORELL, New York, N. Y In this patent use is made of connected number wheels, a spindle and a stop bar ranging across the wheels, the said wheels and spindle being adapted to turn loosely one on the other, each wheel having its periphery provided with consecutive numerals alternating with recesses for engagement by a pencil in the hand of the operator, to govern the relative movement of the adjacent wheel and spindle, the stop bar turning with the spindle and forming a stop for the pencil or tool.

SPINDLE LOCK.—MATTHEW OMALIA, care Reynolds Brothers, 128 Coal Exchange Building, Scranton, Pa The engraving illustrating this lock gives a view partly in elevation and partly in section, showing the lock complete. The more particular purpose of the invention is to provide an improved lock for preventing the removal of a spindle, such, for instance, as is commonly employed in factory work,

SPINDLE LOCK

from its mounting, yet allowing the spindle all the freedom of motion which it now has, and also permitting the removal of the spindle when the operator wishes to release the lock. Means provide for mounting the latch in position and there is a special provision for supporting the latch by aid of a rivet; and since the latter has been used means provide for the rivet being headed up the second time.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

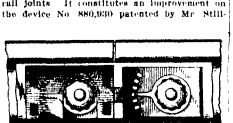
It runs on foot and leaves both hands free to operate tools. Write for it to-day. W. E. Hamilton, 484 Lakewood Ave., Lexington, Ky.

PUMP VALVE.—ERNEST D. ORTON, Farmersville, N Y The engraving in this case represents a vertical section of a valve for suction pumps, and one readily accessible for the purpose of cleaning or repairing An object of the invention is the provision of a

PUMP VALVE

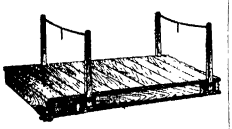


valve with means for adjusting the tension of said valve, for elevating water at different heights Further, to provide a valve with means for lifting the same by direct downward contact, to reduce the water limitioned above the valve The valve may be adjusted to any pump already in use by cutting out the old valve and lowering into its place this improved valve, which is readily secured in position by means of lugs.

Prime Movers and Their Accessories.

ROTARY ENGINE—T IDBAL, Camden, N J An object here is to provide a novel form of engine in which a single rotary piston is acted on at several points in its rotation by the admission of fresh air Means are provided for operating the abutment valves, so as to insure the greatest economy in the workings of the engine Means provide for controlling the exhaust ports The inventor accomplishes this by a series of valves whose position may be simultaneously adjusted by the manipulation of a single lever A further object is to provide means for regulating the steam inlet

Railways and Their Accessories.



NUT LOCK—CLAUDE B STILWELL, P O Box 522, Savannah, Ga This invention relates to nut locks, and is particularly applicable to the construction of such devices when used in securing the nuts of the bolts which attach the fish plates to the rails at the rail joints It constitutes an improvement on the device No 880,960 patented by Mr Still-

NUT LOCK

well In the present case, the invention contemplates the use of improved means for preventing the nut from rotating on the bolt, and the principal object of the invention is to provide means for covering the mechanism of the device so as to prevent it from being injured or displaced The illustration in the larger figure represents a side elevation of a railroad rail joint showing a modified form of the invention, and the smaller is a prospective view of a modified form of the lock plate

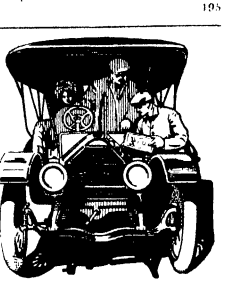
CAR STAKE POCKET.—CHARLES PYLE, Ironwood, Mich This invention refers to load retaining means for vehicles, and especially to means whereby side stakes are positioned upon platform and logging cars, and which may be held in vertical position against

CAR STAKE POCKET

the pressure of a load, or may be easily released from a position of safety A further object is to provide a stake pocket capable of disengaging the stake quickly without time being lost in cutting off the stake close to the pocket, and the consequent removal of the short piece therefrom; and has for a further object the provision of means whereby any form of stake may be used, or in which a particular shaped set of stakes may be carried The illustration shows the device applied to a car platform

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.



Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. Be full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12522) H L W asks What causes the changes of the barometer at a given point? A The changes of the barometer at any given place are caused by the change in the pressure of the air about that place The atmosphere has waves in it of greater and less pressure, and these waves move around the earth, following each other much as waves chase each other over the ocean A high follows a low, and a low follows a high A low barometer has been traced for about five weeks from the coast of Asia across the Pacific, America, the Atlantic, Europe, and into Siberia While there are erratic changes there is also a general flow of areas of greater and of less pressure to which the barometer responds

(12523) A E H asks Some months ago you published in your Answers to Correspondents an explanation to show that if an object sinks at the surface of water, it will sink to the bottom, no matter how deep the water may be the great pressure at increasing depth having no effect to keep the object suspended I inclose 10 cents in currency and postage Will you kindly send me a copy of your paper containing that statement? Or, if you prefer, simply give an answer in an early issue, where I shall see it as I buy the SCIENTIFIC AMERICAN regularly A The question of sinking or floating is determined by a law known as the Principle of Archimedes It is that an immersed body is buoyed up by a force equal to the weight of the fluid displaced If a body under water weighs less than the water it displaces it will rise If it weighs the same as the water it displaces it will remain where it is If it weighs more than the water it displaces it will sink And if it begins to sink and no change is made in it, it will continue to sink, because it is more compressible than water If it is heavier than water at one level still more will it be heavier than the water at a lower level, since in going to the lower level it has been compressed by the water more than the water itself has been Our attention has lately been called to the case of the submarine, which can be held at a selected depth But the volume and the weight of the submarine are changed by admitting or removing water to adapt it to its desired depth, and it is made to have just the weight proper for the level it is to maintain If it should begin to sink and no change were made in it, it would continue to sink to the bottom It is no exception to the general case The expression you use "the greater pressure at increased depth having no effect to keep the body suspended," is not quite correct It has an effect but not enough effect To put it in another way, the sinking body becomes denser more rapidly than the water does at increased depths, and so must continue to sink This is one of the questions of frequent recurrence We recently gave the coefficient of compressibility of steel, one of the hardest metals and least compressible It will be found in Vol 124, No 125, to which we refer for further statement

(12524) J S J says I am installing an electric bell circuit with three bells and four cells attached Will you please tell me in your Notes and Queries lines which is the most desirable to connect cells in series, in multiple or in series multiple A Probably four cells in series will be sufficient to ring three bells, though only a trial can determine that matter If it is not sufficient add more cells The usual mode of arranging a bell battery is in series When a sufficient number of cells have been put in series to give the voltage for the bells, you can get the necessary amperes by a second series of the same number of cells in multiple A multiple arrangement of single cells is not desirable

(12525) E P W asks: If a locomotive drawing ten passenger cars running at a rate of speed of 40 miles an hour, should have every wheel of the locomotive and of each car securely locked at the same moment, would the momentum of the train stop at the same time? And what would be the probable effect on the train by the locking of each of the wheels at the same moment? A If the wheels were locked by the brakes so that they ceased to revolve, the train would slide on the wheel rims until its momentum was exhausted If you mean, however that the wheels are to be locked to the track suddenly we can only say that neither wheels nor car bodies, nor any other moving particle, can ever be *instantly* stopped except by *infinite* force, that is, by a force greater than any known quantity No moving train could have its momentum instantly taken away, the attempt to do so has destroyed much rolling stock in railroad wrecks.

"Spare the Oil and spoil the Car"

PENNIES saved on oil or grease may mean dollars spent in up-keep—not to mention annoying delays or the shortened life of your car.

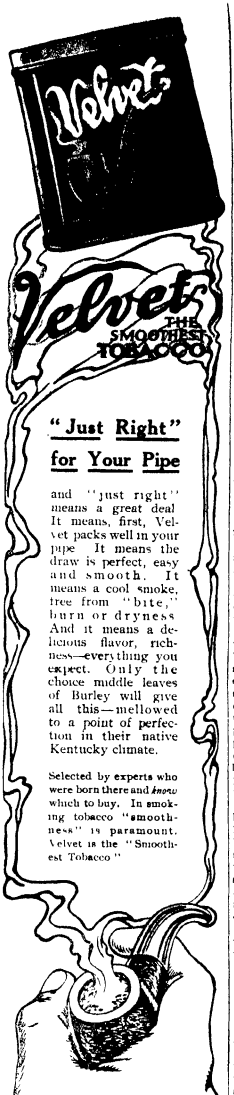
For motorists who recognize the economy of using the best oil we have produced Polarine.

It is not a low-priced oil. But in the long run it will prove sound economy.

Polarine Oil goes through special processes of distillation, pressing and reducing. It is then carefully cleaned and filtered to remove impurities and free carbon. This secures the correct lubricating qualities for gas engine use.

Polarine leaves no appreciable carbon deposit.

Its consistency or "body" is not materially affected by either high or low temperatures. It flows freely down to zero.



Polarine

The Polarine Brand covers:
POLARINE OIL (in gallon and half gallon sealed cans, in barrels and half barrels), POLARINE TRANSMISSION LUBRICANTS, POLARINE CUP GREASE and POLARINE FIBRE GREASE.

These lubricants cover the needs of every part of the car

Send to our nearest agency for "Polarine Pointers" which includes hints on the care of motor cars

Standard Oil Company
(Incorporated)

"Just Right" for Your Pipe

and "just right" means a great deal It means, first, Velvet packs well in your pipe It means the draw is perfect, easy and smooth. It means a cool smoke, free from "bite," burn or dryness And it means a delicious flavor, richness—everything you expect. Only the choice middle leaves of Burley will give all this—mellowed to a point of perfection in their native Kentucky climate.

Selected by experts who were born there and *know* which to buy. In smoking tobacco "smoothness" is paramount. Velvet is the "Smoothest Tobacco"

At all dealers, but if yours is out we'll send you a can for a dime if you live in the U. S. A

Spaulding & Merrick

"Ask the man who smokes it"

Convert Abandoned Mills into Electric Power Plants

(Continued from page 195.)

wires at a high voltage over an extended area there is little difference from a point of view of risk to life between one high voltage and another. Only the best of construction should be used and proper provision for safety must be observed. This is not always the case with distribution systems having a voltage of about 2,000, and for that reason a voltage of 10,000 volts has an added advantage.

With a co-operative system the farmer can erect much of the line work himself, thus accomplishing a saving. Poles may be prepared in the winter time when work is not heavy. In some of the newer transmission installations, concrete poles are used with success and improvement in appearance. They are about 35 feet high, tapering from 15 inches in diameter at the base to 6 inches at the top, reinforced throughout with steel rods Such poles can be made at home at any convenient time of year

With a high voltage system and proper line construction the poles ought to be spaced not less than 200 feet apart and should take the most direct route from the source of electric supply to the point at which current is to be used The immediate land over which the line passes should be assigned as a permanent right of way, proper provision for legally doing this and protection from malicious or meddlesome persons being made

The cost outlay in constructing such a distribution system would be found remarkably small if the farmer should make and haul all poles and cross arms and supply the rough labor for setting poles and stringing wires The actual expenditures would, therefore, be only in purchasing wire, insulators, guys, etc., that could not be had on the ground The number and size of transformers and meters would vary according to the individual demand and local conditions These, however, each one should buy himself in the same manner that he would electric motors and lamps With such a system, all purchasing should be taken care of co operatively, thus insuring to the individuals the benefit of quantity prices In conjunction with the power plant a creamery, laundry and grist mill could be equipped and operated at very little extra expense, as the buildings and power available would prove ample for this

The total cost of the undertaking, as here outlined, including power plant and line construction, would be in the neighborhood of $30,000, to be borne by twelve subscribers, thus each must contribute the equivalent of $2,500 cash Certainly a successful farmer having upward of 200 acres should be able to muster this amount, if the investment will result in economy and safety

The cost of operating a water power plant is naturally small, and it consists merely of the interest and depreciation charges, and the salary of one or possibly two men in attendance If the plant is to give day and night service, then two men will be required, otherwise one is all that is necessary The farmers' need for lighting during the early hours of the morning and the convenience of having current for this purpose at any time of night or day makes it a better equipment to have two men available for duty The total salaries on this basis would approximate $2,000 per annum and with 5 per cent interest and a like amount to cover depreciation and maintenance of the entire equipment, we have a total yearly cost of $5,000

In regard to the amount of electricity that each farmer would be likely to use with a total equipment averaging in capacity the equivalent of 50 electrical horse power, we are safe in assuming a load factor of five to ten per cent for eight hours per day

Taking the lower figure, this represents 20 horse power hours per day for each of the twelve farmers, for which a rate of 10 cents per electrical horsepower hour would be a proper charge for the subscribers to pay for their service. This would, therefore, provide a minimum yearly income of $6,000, assuming that this average amount of electricity is consumed for 200 days each year. Hence, on the basis of this somewhat over-conservative estimate, there would be sufficient yearly return to pay the cost of full operation and insure a 20 per cent margin for profit. The plant discussed is of sufficient capacity to take care of the maximum demands of all the subscribers at any one time, and as two power units would be installed of equal size, either one would have capacity for the average demands

This outline of a real practical opportunity for farm betterment is only typical of several that the writers themselves have observed, and, doubtless, there are hundreds of small water falls of this character available if we but look for them

To be sure it is hardly to be expected that the farmer as such is going to unravel the mysteries or details of a problem of this kind alone, but we shall expect his interest and foresight in recognizing the merit of such a scheme, and, once finding out its practicability mastering the situation by so organizing that it may be successfully carried out.

The manufacturer finds capital and skilled assistants to convert his new ideas into practical commercial form, and the farmer to be successful must follow the same course.

Stress in Aeroplanes in Curvilinear and Fancy Flight

(Continued from page 189.)

frolic and fantastic flying

In order to obtain actual data for the fluctuations of stress in an aeroplane in varied flight, I would suggest that a record be taken of the stress or strain of some tension or compression member of the machine in action, or simpler still, perhaps, that a record of the aeroplane's acceleration be taken, and more particularly its transverse acceleration A very simple device to reveal the transverse acceleration of the aeroplane in flight would be a massive index elastically supported A lath or flat bar stretching lengthwise of the machine, one end fixed, the other free to vibrate, and carrying a pencil along a vertical chronograph drum would serve such purpose. The whole could be incased from the wind as shown in the sketch (Fig 2.)

An adjustable sliding weight could be set to increase or diminish the amplitude of the tracing, and an aerial or liquid damper could be added to smooth the tracing The zero line would be midway between the tracings made on the drum by the stationary instrument when resting alternately in its normal position and upside down, the distance from this zero line to the actual tracing of the stationary instrument would be proportional to the aeroplane stresses in level rectilinear flight, while in level flight on a curve,

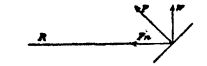

Fig. 4.—Resultant force due to horizontal wheeling.

either horizontal or vertical, the deviation of the mean tracing from the zero line would indicate the actual stress in the machine during such accelerated flight. Of course the drum could be omitted and a simple scale put in its place, so that the pilot could observe the mean excursion of the pencil or pointer from instant to instant. Also, the damping of such excursion could be adjusted to any amount in the proposed instrument, if the vibrating lath fitted its incasing box closely, with an adjustable passage for the air as it moved to and fro, or if light damping wings were added to the lath, or flat pencil bar.

Another method would be to obtain by instantaneous photography the position of the centroid of the aeroplane at a number of successive instants, from which could be determined its speed and path, or V and R of the first equation, by which data therefore the stress could be read from the first table.

Perhaps the simplest plan would be to add an acceleration penholder, with its spring and damper, to any recording drum the aeroplane may carry for recording the air pressure, temperature, speed, etc. Indeed, all such records could be taken on a single drum.

PENNSYLVANIA R. R.

NEW YORK AND CHICAGO BETWEEN SUNS

Through the uplands and valleys of Pennsylvania, over the plains of the near west is a pleasant route to travel in the summer-time. Especially on a train of the highest grade over a completely rock-ballasted roadbed. The perfect appointment of the train yields the maximum of enjoyment; the lay of the land insures the minimum of seasonal discomfort.

The "Pennsylvania Special" makes the run mostly in the cool of the evening and at night. This is the ideal time for travel. It is the business man's closed period of the day.

The "Pennsylvania Special" is in the highest respect the Busy Man's train. It runs in his idle hours while business rests, and delivers him when the trade of the day begins.

Economy of time is the pith of an undertaking.

The "Pennsylvania Special" the original 18-hour train, all-steel, perfectly appointed, leaves Pennsylvania Station, one block from Broadway at 32d Street 4.00 P. M. and arrives Chicago 8.55 next morning. It leaves Union Station, Chicago, 2.45 P. M. and arrives New York 9.40 A. M. next day.

Other fast trains.

A PLAN *for* INVESTORS

We invite your inquiries regarding our plan for the purchase of Railroad and Industrial Stocks whereby WE COMBINE Higher Income, Increase in Value, Absolute Safety, on purchases of active listed securities

We will send you upon request description of this plan, which is superior to buying stocks upon partial payments without obtaining partial payment advantages.

A score of devices, more or less simple, but suitable for revealing the varying stress in an aeroplane, will occur to any engineer who may give the subject his attention, and it is desirable that some one obtain roughly accurate data for the stresses developed in actual flight. This is desirable in the interest both of aeroplane design and of prudent manipulation.

It is commonly supposed by aviators that the increment of speed due to diving is very prodigious. An easy formula will determine the major limit of such speed increment. If the initial and natural speed of the aeroplane be v, and the change of level in diving be h, while the speed at the end of the dive is V, the minimum change of level necessary to acquire any increment of speed $V\text{-}v$, may be found from the equation

$$h = (V\text{-}v)/2g$$

And if, as before, g be taken as 22 miles per hour, the equation reduces to the convenient formula

$$h = (V\text{-}v)/30$$

in which V and v are taken in miles per hour. Assuming various values for V and v, the following table has been found for the corresponding values of h in feet.

Minimum Change of Level Necessary to Produce Various Speed Increments.

The Speed, v, of the Aeroplane.	Increments of Speed, $V\text{-}v$		
	Miles Hour 10.	Miles Hour 20.	Miles Hour 30.
M. H.	Ft.	Ft.	Ft.
30	23.3	53 3	90 0
40	30 0	66 7	110 0
50	36 7	80 0	130 0
60	43 3	93 3	150 0
70	50 0	106 7	170 0

For example, if the natural speed of the aeroplane in level flight be 50 miles an hour, and the aviator wishes to increase the speed by 20 miles per hour, he must dive at least 80 feet, assuming that the aeroplane falls freely, like a body *in vacuo*, or that its propeller overcomes the air resistance completely; otherwise the fall must be rather more than 80 feet.

A very instructive and spectacular contest could be arranged to determine which aviator could dive most swiftly and rebound most suddenly, the prize going to the one who should stress his machine most, as indicated by the accelerograph above proposed; but to avoid danger the contest would have to be supervised by competent experimentalists, and would best be conducted over water. It is safe to say that more than one well known aeroplane would be denied entry in such a contest, for lack of a sufficient factor of safety.

What the Mirror Does to You

(Continued from page 190.)

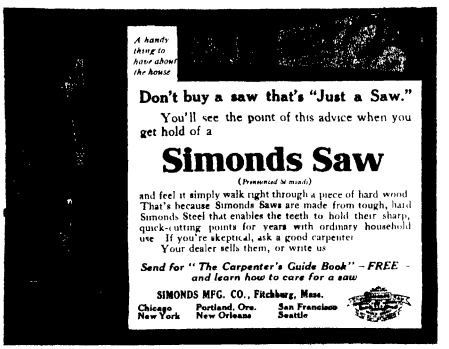
his clothing, only he would have to put his right glove on what used to be his left hand!

While there is a certain comic element in the point of view thus presented, it has as a matter of fact a number of important serious applications. The first point to note is that no ordinary operation, such as mere rotation or inversion, can possibly effect the change which the mirror produces. No turning or twisting of your right hand glove can ever make it into a left hand glove—except that one operation of "turning it inside out." With most ordinary objects this operation is of course quite impossible. Two ordinary objects therefore which are related to one another as the right hand is to the left, or in other words, as one object is to its mirror image, cannot by any sort of transposition be made to coincide, like two congruent figures of geometry.

This fact has found an interesting and important application in organic chemistry. It is found that certain chemical compounds occur in pairs, the two members of each pair being practically identical in all their properties, but while one rotates the plane of polarization of polarized light to the right, the other rotates the same by an equal amount to the left. Now the curious thing is observed, that in every case in which the formula of such a compound is known, it is found to contain a so-called asymmetric carbon atom, that is to say, one which is linked to four different groups or radicles. An example of this kind is lactic acid, whose formula is

It will be observed that the central carbon atom has four unlike groups attached to it. If a solid model of such a formula is made, with the links extending evenly out from the central carbon atom, it is found that there are two possible arrangements of the groups—and the two are related to each other as an object is to its mirror image, or as the left hand is to the right.

This is shown in our last illustration (Figs. 6 and 7), in which the central carbon atom of the lactic acid molecule is represented in the customary manner by a regular tetrahedron, or four-angled solid. Each corner of this tetrahedron represents one of the bonds or affinities of the central carbon atom. The four groups attached can be arranged in two and only two insuperposable arrangements, as shown, of which the one is the mirror image of the other.



This is true only as long as the groups attached to the central carbon atoms are all dissimilar, as is the case in lactic acid. As soon as two or more of them are alike, only one arrangement is possible. The fact that such an "asymmetric" carbon atom occurs in all optically active carbon compounds whose formula is known (and they are exceedingly numerous) appears too significant to be ascribable to accident, and it is customary to regard the two twin forms—optical isomers as they are called—as represented by the two possible space formulæ, although there is at present no means of identifying each member of the pair of compounds with a particular one of these two formulæ.

The reader will recall that in analytical geometry also it is necessary to distinguish between two kinds of systems of rectangular co-ordinates, which are related to one another as object to image, or as the right hand is to the left hand. Here also the two arrangements are "insuperposable," and form two distinct systems. Since mathematical treatment extends to innumerable applications of all kinds in different branches of science, this relation of the object to its image is one of pretty general interest.

A Forest Service Circular on "Chaparral"

BULLETIN 85, entitled "Chaparral," by Fred G. Plummer, geographer of the Forest Service, is a publication dealing exclusively with a type of plant formation that has never before been made the subject of study. It is a work that is justly called the pioneer in its field. Chaparral is an Americanized term for a distinctive type of growth, which Mr. Plummer describes as a mixed forest of stunted trees, and is the result of peculiar climatic conditions. It forms an intermediate stage between a true desert and timberland. The author classifies wild lands into eight distinct types, as follows: desert, barren, grassland sagebrush, brushland, chaparral, woodland and timberland. The first four and a part of the fifth do not bear trees, the balance are forested areas. Chaparral is, therefore, a general term for a type of mixed growth of stunted arborescent plants, and is not, as is generally supposed, a name given to one particular species of plants.

The circular deals with the natural and artificial forces now in operation, which tend to limit or extend the range of distribution of chaparral forming species. This includes, not only historical records of past forest conditions in a chaparral region, but also a consideration of its present condition in relation to forestry and conservation. Here the chief topics are geographical conditions in the chaparral area; chaparral and the water supply; vertical range of chaparral; composition of chaparral; amount of shade produced, and the value of the different species. Although the central feature of the treatment is the effort to keep clearly before the reader the value of chaparral as a conservator of water, Mr. Plummer also discusses the commercial uses of

Don't buy a saw that's "Just a Saw."

You'll see the point of this advice when you get hold of a

Simonds Saw

(Pronounced S mands)

and feel it simply walk right through a piece of hard wood. That's because Simonds Saws are made from tough, hard Simonds Steel that enables the teeth to hold their sharp, quick-cutting points for years with ordinary household use. If you're skeptical, ask a good carpenter. Your dealer sells them, or write us.

Send for "The Carpenter's Guide Book" – FREE – and learn how to care for a saw

10% Oversize Adds 25% to the Mileage

Goodyear No-Rim-Cut tires—the patented tires which cannot be rim-cut—are 10 per cent oversize.

That means 10 per cent more air—10 per cent greater carrying capacity—at no extra cost. And that, with the average car, adds 25 per cent to the tire mileage.

These two features together—No-Rim-Cut and oversize—under average conditions cut tire bills in two. Yet they cost the same as standard old-type tires.

GOODYEAR No-Rim-Cut Tires
With or Without Non-Skid Treads

As a result, the demand for these tires has three times doubled in the past two years. To meet that demand we are equipping to make 3,500 tires per day.

Motor car owners are adopting these tires as fast as they find them out. The advantages are too apparent—the savings too big—to miss. If you pay tire bills let us tell you how to cut them down.

Our Tire Book—based on 12 years of tire making—pictures and explains many facts you should know. Ask us to mail it to you.

THE GOODYEAR TIRE & RUBBER COMPANY, First Street, AKRON, OHIO
Branches and Agencies in 103 Principal Cities (988) *We Make All Sorts of Rubber Tires*

some of the species for fuel, fencing, forage, bee-pasturage, etc.

The forester's point of view is also vividly illustrated in the chapters dealing with methods of protection against fire and artificial restocking of more valuable species after fires. Not only is the work entirely new in substance and its method of treatment, but it is fully abreast of the latest research, as shown particularly by the nomenclature of the species considered. The illustrations are numerous, wisely chosen and well executed. The pen drawings of the principal species of chaparral are excellent and all the half tones are clear. The addition of a small map engraved in colors, showing the distribution of chaparral, is a unique and valuable feature of the illustrations.

While this bulletin is intended primarily as a work for foresters in western United States and for forest students in general, and will probably be read, chiefly by technical foresters, nevertheless its readable style, choice and arrangement of subjects and emphasis laid upon scientific accuracy, cannot fail to commend the publication to any one who may be interested in reading the story of our large areas of stunted forests in the West.

The Current Supplement

IN the companion issue, No 1860, of our SUPPLEMENT, Harold J Shepstone contributes an article on the Potter's Clay Industry.—A very interesting suggestion for a new method of estimating the duration of geological ages is made by Mr Arthur Holmes.—We bring some new information regarding that important modern development, the Diesel engine, as applied to marine use.—The electrolytic smelting of iron has for some time been attracting attention. Consul L. J Fuller, of Gothenburg, Sweden, reports on the production of pig iron by electricity.—The application of metallographic diagnosis to the effect of mechanical treatment on the structure of metals is discussed by our Paris correspondent.—The fifth instalment of *Donald Murray's* article on Printing Pictures appears in this issue.—The electric locomotive for the line running through the tunnel in the Lotschberg is described by our English correspondent.—Mr Feldhaus gives us an illustrated account of the "Evolution of the Umbrella."—Prof Wiener discusses some of the dangers of aeronautics, and remedies against them.—R A Smith gives an account of the highways which the Romans built through and about the present site of London.—A. E Outerbridge discusses the uses and limitations of manganese and silicon in foundry practice.

An Exhibition of Labor-saving Appliances

THE United States Government Exhibit of Labor Saving Office Appliances was held on two floors of the Union Building in Washington city, July 6th to 15th, and the display is said to have equaled those of the Madison Square Garden and the Chicago exhibit of last March. Being held under government auspices the display involved no cost to the exhibitors for space, light or heat and the large market promised by the government service attracted manufacturers from all directions, the articles exploited ranging from lead pencils to the most complicated forms of apparatus employed in office work. Good attendance was assured as government employees received tickets for the exposition and were granted leave for the purpose of attending and opportunities were afforded for their recommending such appliances as appealed especially to them. Of the hundreds of appliances shown, it is doubtful if there is a single one which would not find a useful place in any large office establishment.

Exchange Professor in France.—The exchange of professors recently arranged between Harvard University and the French Ministry of Public Instruction goes into effect next winter, with W. M. Davis (recently exchange professor in Berlin) as the first exchange professor in France. Prof Davis will lecture on land forms. Prof Diehl, of the Sorbonne, will lecture on Byzantine history at Harvard.

Electricity

Fiftieth Anniversary of the Dynamo.—Fifty years ago Sr. Antonio Pacinotti invented the first commercial type dynamo. This event is soon to be celebrated in Pisa. At the time he invented the dynamo, Pacinotti was a student at the University of Pisa. He used a ring armature of the type now known as a "Gramme ring," having been reinvented by Gramme in 1870. It was not until 1881 that Pacinotti's dynamo attracted much attention, when, at the Paris Exposition, a diploma was awarded to the Italian inventor.

Railroad Car for Transformers.—A striking illustration of the enormous size of some of the transformers made in these days is shown by a new type of car built for transporting these transformers by rail. The car referred to is provided with a cut-out at the center, so that the floor is brought to within two feet, two inches of the tops of the rails, this being necessary to give sufficient clearance under bridges. The car is 35 feet 5 inches long, and in the cut-out portion will carry a load of 150,000 pounds.

Street Lamps of All Kinds in Chicago.—Figures given in the recent annual report of the Department of Electricity of Chicago, and quoted by the *Electrical World*, show that the total number of public street lamps in service on December 31st, 1910, was 37,994. Of these, 12,868 were municipal electric-arc lamps, 693 rented arc lamps, 11,980 gas-mantle lamps, 5,426 gas flat-flame lamps and 7,319 gasoline lamps. The cost of rented arc lamps is $75 a year, municipal arc lamps $61.96 a year, mantle gas lamps $18.91, open-flame gas lamps $15.41, and gasoline lamps $26.40.

An International Electric Railroad.—An electric railroad is to be built which will run in three countries, Italy, Switzerland and Austria, and it will greatly shorten up the distance by rail from Milan to Munich. On the Italian side it starts from Tirano, which is the terminus of the Valtelina electric road, and crosses the Swiss frontier by a five-mile tunnel through the mountains, reaching the Munster Valley. It then crosses into Austria to Mals, and this point will be connected to Landeck by a line which the Austrian Government is to build. This latter point lies on the railroad leading to Munich. It is probable that an electric section will be also run from Landeck to Munich.

Energy Generated in London and in New York.—The returns issued by the London County Council, and quoted by the *Electrical World*, relating to the amount of electricity generated in and around London, show that in London the borough councils generated or purchased 91,851,181 kilowatt hours, of which 75,115,968 kilowatt hours, or 82 per cent, were sold. Information regarding the kilowatt-hours generated by the London companies is not available, but they disposed of 137,211,288 kilowatt-hours. Whether this included that used by the railways is not stated. In New York city the amount of energy generated by the public-utility companies last year is estimated to have been 1,750,000,000 kilowatt-hours.

Mechanical Annuator.—A novel "current gage" has just been invented, which is designed to give a fair approximation of the current flowing through a conductor without cutting the conductor or interfering with its operation in any way. The device consists of a U-shaped magnet of laminated soft iron, secured to a handle, an arm is fulcrumed to the handle with one end serving as an armature directly over the poles of the magnet, and the other is fitted with a leaf spring engaged by a set screw on the handle, whereby the armature may be moved into or out of engagement with the poles of the magnet. If it be desired to measure the current in a conductor, the U-shaped part is placed over the conductor, and is electro-magnetically energized thereby. The set screw is then turned to force the armature away from the pole and when it has been moved far enough to spring away, the number of amperes passing through the conductor will be indicated by a hand on the set screw, which sweeps over a graduated dial.

New Practical Books

Popular Handbook for Cement and Concrete Users

By MYRON H. LEWIS, C. E., and ALBERT H. CHANDLER, C. E. Octavo, 430 pages, 126 illustrations. *Price, $2.00.*

¶ A concise and comprehensive treatise on the principles and methods employed in the manufacture and use of concrete and its products in all classes of modern works. It is a standard work of reference covering the various uses of concrete both plain and reinforced. Everything of value to the concrete user is given, including kinds of cement employed in construction, concrete architecture, inspection and testing, waterproofing, coloring and painting, rules, tables, working and cost data. It is a thoroughly practical work, clearly written, systematic and logical in its arrangement, broad in its scope and gives a lucid explanation of, and a clear insight into the fundamental principles employed in concrete design and construction. The practical value of the book is enhanced by over thirty-five useful tables, and concise statements of rules and methods.

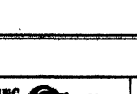
Drop Forging, Die Sinking and Machine Forming of Steel

By JOSEPH V. WOODWORTH, author of "Dies, Their Construction and Use," "Punches, Dies and Tools for Manufacturing in Presses," etc. Octavo, 340 pages, 300 illustrations. *Price, $2.50.*

¶ A complete practical treatise on the hot and cold machine forming of steel and iron into finished shapes, together with the tools, dies and machinery involved in the manufacture of duplicate forgings and interchangeable hot and cold pressed parts from bar and sheet metal. It is a comprehensive and modern work, written by an expert, and treating fully on modern shop practice, processes, methods, machines, tools and details.

Standard Practical Plumbing

By R. M. STARBUCK, author of "Modern Plumbing Illustrated," etc. Octavo, 406 pages, 347 illustrations. *Price, $3.00.*



¶ This is a complete practical treatise and covers the subject of modern plumbing in all its branches. It treats exhaustively on the skilled work of the plumber and the theory underlying plumbing devices and operations, and commends itself at once to everyone working in any branch of the plumbing trade. A large amount of space is devoted to a very complete and practical treatment of the subjects of hot water supply, circulation and range boiler work. Another valuable feature is the special chapter on drawing for plumbers. The illustrations, of which there are three hundred and forty-seven, one hundred being full page plates, were drawn expressly for this book and show the most modern and best American practice in plumbing construction.

Any of these books will be sent, postpaid, on receipt of advertised price

THE SEBASTIAN 15-INCH ENGINE LATHE
HIGH GRADE LOW PRICE
Automobile Builders, Garages, Repair and General Jobbing Shops find this the ideal lathe for their work. Catalog free. The Sebastian Lathe Co. 120 Culvert St., Cincinnati, Ohio

Friction Disk Drill
FOR LIGHT WORK.
Has These Great Advantages:

The speed can be instantly changed from 0 to 1000 without stopping or shifting belts. Power applied can be graduated to drive, with equal safety, the smallest or largest drills within its range—a wonderful economy in time and great saving in drill breakage. ☞ Send for Drill Catalogue.

W. F. & Jno. Barnes Company
Established 1872
1999 Ruby Street. Rockford, Ill.

The Detroit Combination Tool
A TOOL-SHOP IN ONE TOOL

Rotary blower forge, geared drill press, geared emery wheel, vise, pipe-vise, anvil and tools in one. High grade. Portable. Weight, 175 lbs. Price $50 cash, f. o. b. Detroit. This wonderful invention, patented, protected, is absolutely essential for automobile owner, farmer, driller, thresherman, logger, ranch, repair crew. The best selling article since the sewing machine. We want

Agents. Responsible men can secure exclusive territory yielding from $60 to $100 per week

Detroit Tool Company
Dept. 3 Detroit, Mich.

ENGINEERS' TAPER, WIRE AND THICKNESS GAGE

A set of gages in compact form for marine engineers, machinists, etc. Taper shows thickness in 16ths to 2½ in. on one side, taper side to scale. English standard wire gage with 3 faster gages over 4 in. long. All held into one 4½ in. long, convenient for pocket. Price $6.50.

Send for 27 page catalog No. 19 B. of Fine Tools.

Science

International Aeronautical Congress.—The fifth international aeronautical congress will meet at Turin October 25th to 31st, 1911, under the presidency of Commandant Renard. The last congress met at Nancy in September, 1909

A Language of 300 Words.—In the more inaccessible parts of the Sierra Madre Mountains, in northern Mexico, live a curious people called the Tarahumaris Many of them dwell in caves, but they have also small villages, all of them about 8,000 feet above sea level The Tarahumaris are small in body, but possessed of much endurance Their only food is maize, and they manufacture a drink called teshuin, from the same cereal Their language is limited to about 300 words, and they cannot count beyond ten.

Color-changing Paints.—Members of the Physical Society in London were greatly interested at a recent meeting by an exhibition of specimens of paints which change their color with variations of the temperature One of these paints is red at ordinary temperatures, but turns black in a few seconds when warmed in front of a stove or otherwise heated to 206 deg F Another paint is yellow until heated to a temperature of 113 deg F, when it becomes dark red They are called "heat-indicating paints" but are little more than scientific curiosities

Contaminating Gases Turned to Use.—An instance of the transformation by scientific means of a deleterious into a useful substance is furnished by a process employed in Germany in connection with the manufacture of superphosphate fertilizer where apatite is used The large volumes of hydrofluoric acid that are given off seriously contaminate the atmosphere, but by the German process these gases are recovered in the form of fluosilicic acid, which is used in the manufacture of artificial stone for hardening soft limestone and sandstone, and for other purposes

Filtered Water in Bamboo Stems.—Yapp, the English naturalist who has explored the mountain ranges of the Malay Peninsula, reports the fact, not generally known, that in several species of bamboo the hollow internodes—the parts of the stems between the joints—are stored with large quantities of naturally filtered water The knowledge of this fact might be of great service in an emergency Mr Yapp also discovered, on his last visit, two species of ferns, growing on trees, whose thick, fleshy stems are filled with galleries tunneled by ants, the ferns thus forming living nests for the ants

The John Scott Medal for McFarlan Moore.—Mr D McFarlan Moore has been awarded the John Scott Legacy Medal and Premium by the city of Philadelphia upon the recommendation of the Franklin Institute. The award is made in recognition of Mr Moore's scientific investigations in the development of the art of vacuum tube lighting, covering a period of many years Mr. Moore's system, as our readers know, consists briefly in converting electrical energy into light by passing an alternating current of electricity through rarefied gases in glass tubes By a variation in composition of the gases in the tubes, and the degree of their rarefaction, the color and intensity of the light produced are controlled.

Fever in Plants.—Not only animals but plants may suffer and die of fevers, is the conclusion reached by the French savant Du Sablon When a human being has a fever he loses flesh on account of the increased combustion, the quantity of carbonic acid respired from the lungs being augmented from 70 to 100 per cent A plant attacked by a fever, which may be caused by a wound, rapidly consumes its reserves of organic matter and becomes enfeebled, sometimes sufficiently to cause its death Du Sablon has experimented with potatoes rendered feverish by cutting them. The temperature soon rises about one degree, and the quantity of carbonic acid given off increases several hundred per cent. If the potato survives, its "respiration" after a few days becomes normal, but it falls into an enfeebled state, resembling that of a person convalescent from a long fever.

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty Eighth Edition of
"The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by ALBERT A. HOPKINS, Query Editor of the Scientific American

THIS is practically a *new book* and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters I Accidents and Emergencies. II Agriculture III Alloys and Amalgams IV Art and Artists' Materials V Beverages; Non-Alcoholic and Alcoholic VI Cleansing, Bleaching, Renovating and Protecting. VII Cements, Glues, Pastes and Mucilages VIII Coloring of Metals, Bronzing, etc. IX. Dyeing X Electrometallurgy and Coating of Metals XI Glass XII Heat Treatment of Metals. XIII. Circulation

VIEWED FROM BEHIND THE SCENES

Why forced circulations are not worth one hundred cents on the dollar—Advertisers need to know not only how much the circulation is, but also how it was obtained.

By HENRY H. HOWER
Advertising Manager, The F. B. Stearns (Automobile) Co

Slowly, but as surely as the passing of time, a new idea is making itself felt in advertising That idea consists in paying for circulation according to the quality of the publication and its readers—not simply paying for so many sold copies The time is steadily passing when so-many-thousand readers for such-and-such a rate can get any and all business Thinking men are realizing the fact that the hundreds of thousands wasted in advertising can be diverted into producing channels On every side this idea is cropping out

A few years ago—and to-day in many cases—very large circulation meant heavy advertising patronage In some cases this was justified, but very often it was quite the reverse. More and more advertising managers are commencing to think more deeply and to analyze statements which before they had taken for granted

Probably the best example of this class of advanced thinker is E. St. Elmo Lewis Mr Lewis is outspoken in his denunciation of the old method "It is the most erroneous idea in advertising," Mr Lewis said, recently "There is no sense in buying circulation merely as circulation—it is what composes that circulation that counts I wouldn't give two cents for a hundred thousand circulation if I had no way of knowing or finding out something *about* that circulation"

There are publications of 50,000 in this country whose columns are worth more to the majority of advertisers than others of double, and even treble that figure Personally, I would willingly pay *twice as much* for space in the former as in the latter. And the time is coming when *valuable* circulation—among *quality* readers—will win its own battle

Listen Several years ago I became connected with a small semi-trade paper in an executive capacity Shortly after taking up my work, there came one day the representative of a "subscription and circulation bureau" To cut a long story short, he offered to get me *as many thousand subscriptions as I wanted* in any State or States desired—to deliver them within sixty days and to conform to the post-office regulations. All this without any effort on my part, but with considerable expense Suppose all this had been done—the circulation boosted to ten or fifteen thousand—aggressive advertising men put in the field The business would have come in, without doubt

How is the advertising manager to know that some of the various publications he is using are not doing these very things? This may seem an extreme position, and it is doubtless open to criticism, but there is more truth in it than many will care to admit

I know of a certain publication selling for something like fifty cents a year which has recently secured contracts for automobile advertising Cannot the wisdom of the selection of such a medium as this be criticised?

A little test I made of a large list of publications shook up my ideas in a good many ways But above everything else I found that there was a greater difference between well-known periodicals than I had dreamed of before The idea of paying for *the quality* of the publication and its readers means a good deal more to me now than it did then

And one thing more Quality circulation cannot be forced A publication of little merit cannot get—*and hold*—such readers It's the genuine merit of the publication that is responsible and there is nothing in a strong drift toward those publications which have the merit.—*From Printers' Ink, July 6, 1911.*

HARPER'S MAGAZINE

Thirty-five cents a copy Four dollars a year

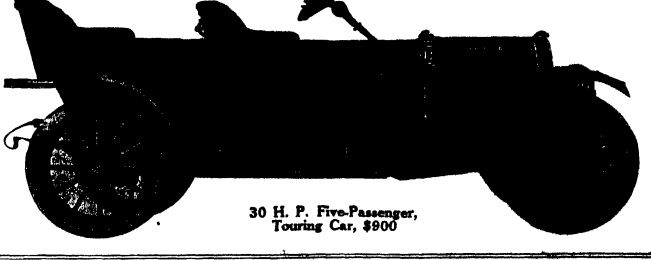
If you care to know more about this—write

Overland

30 Horse-Power Five-Passenger Fore-Door Touring Car—$900

A MONTH ago we made the first announcement of this car. Our prediction came true. The entire industry sat up and had a good look. The day of that announcement dealers wired from almost every section of the country. They came to the factory in droves. Agents that last season bought 100 cars this year contracted for 150 and 200. The dealers from the metropolitan centers advanced their orders in proportion. Others that formerly contracted for 1000 cars signed up for 1500 for 1912. In one week we signed up nearly 8000 cars. One of our dealers alone takes more cars than most manufacturers turn out in a year. For the coming season eighteen hundred dealers throughout America will handle the Overland line.

This car is now ready for demonstration. If the Overland dealer in your town hasn't received one he will in a few days. Wait and see it. To fully understand the exceptional value of this car you have but to compare it with what the entire market has to offer for 1912. Study the specifications below carefully. In what other car will you find such value at such a price? What machine under $1250 can you line up against this and item for item see so much for so little money. When you stop to consider the fine, thorough construction—the heavy drop forgings—the pressed steel frame—the selective transmission fitted with F. & S. annular bearings (which the most expensive cars in the world use)—the 30 horsepower motor, the big wheel base, the fore-door body with door handles and all levers inside the car, you can better realize what an actual advanced manufacturing step this new car is. It is doubtful if any one ever expected so much in an automobile for such a small price.



We urge upon anyone who feels at all doubtful about this statement to take the announcement of any other standard maker and see what he has to offer. Just make a few straight comparisons. Take any other car—compare the wheel base—the size of the motor—the body—the design—the finish—the seating capacity. See if you can purchase this car below $1250. And go further than that—find out how the other cars are made and what they are made of. This will reveal some interesting facts about the economical manufacturing strength of the Overland organization.

Our 1912 catalogue is now off the press. It explains exactly why no other maker in the business can produce this car to sell at this price without losing money. Write for a copy today.

SPECIFICATIONS OF MODEL 59

Wheel base, 106 inches; body, five-passenger fore-door touring, motor, 4x4½; horse-power, 30, transmission, selective, three speed and reverse, F. & S. annular ball bearings, ignition, Dual, Splitdorf magneto and batteries, front axle, drop forged I-section, rear axle, semi-floating; wheels, artillery wood, 12-1½ inch spokes, 12 bolts each wheel; tires, 32 x 3½ inches Quick Detachable; frame, pressed steel; finish, Overland blue; equipment, three oil lamps, two gas lamps and generator; tools, complete set; price, $900.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are striking, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial advancement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

The Mystery of the "Maine"

PRESIDENT TAFT, in asking for an additional appropriation of $250,000 to complete the work of unwatering and disclosing the wreck of the Maine, undoubtedly voiced the opinion of the nation at large when he said: "As long as there remains unexcavated any portion of the mud and debris within the wreck or in its neighborhood, from which evidences may be had of the original cause of the disaster, we shall be derelict in our duty if not prosecuting a further research."

Interest in the extraordinary operations which are being carried on by our army engineers in Havana harbor in the effort to solve the riddle of the "Maine" is more than national. It is world-wide. Both as an engineering work of unusual difficulty and as a determined attempt to get to the bottom of a mystery which is without parallel in naval history, the work which we illustrate and describe on another page of this issue is of profound interest, and the question will naturally arise at this stage of the proceedings as to what promise is afforded of determining with certainty whether the "Maine" was destroyed by an explosion from without or within the ship, and whether the disaster was deliberately planned, or resulted from accidental causes.

The work so far done seems to render the problem more perplexing than ever, for the unwatering of the ship has shown that the destruction of that portion of it where the explosion occurred was even more complete than was supposed. The examination made by divers immediately after the disaster showed that for a length of 70 to 80 feet the sides and decks of the "Maine" had been literally blown to pieces. The double bottom, badly broken up and twisted out of shape, was apparently more or less in place, and it was largely upon the testimony of the divers that portions of the double bottom showed that the plating was bent upwards and into the hull, and that a portion of the keel and bottom had been forced up to a point about 30 feet above where it would be had the ship sunk unimpaired, that the naval court of inquiry found that "the Maine was destroyed by the explosion of a submarine mine, which caused the partial explosion of two or more of the forward magazines."

In the intervening thirteen years, the wreck of the "Maine" has sunk many feet down into the soft mud of the harbor bottom. Judging from the photograph shown on pages 210 and 211, the keel and double bottom in the region of the explosion must have sunk even further than the wreck itself; else this portion of the wreckage would be visible, where the photograph shows an absolutely clear space. It is stated (though we have no official confirmation of this) that soundings in the region of the gap failed to show the existence of the double bottom. It is conceivable that, becoming detached from the rest of the wreckage, its weight has carried it slowly down to the underlying firmer bottom of the harbor, some sixty feet below the surface of the water. In this case, its recovery and thorough examination will prove to be a matter of extreme difficulty. Failing its recovery, the question as to how the "Maine" was destroyed must forever lack a definite and convincing answer.

The mystery of the "Maine" is to-day as profound as ever. Every hypothesis that has been offered presents insuperable difficulties. The suggestion that the deed was done by the Spanish government through its naval or military officers has, from the very first, been scouted by the naval and military men of the United States, who point to the fact that the Spaniards are a proud and a high-minded people, whose naval and military men are above all suspicion of so foul an act as the sinking of the ship of a friendly nation. Furthermore, the events of the war showed the Spaniards were woefully inefficient in the handling of mines and torpedoes, as witness the case of the battleship "Texas," which fouled a floating, Spanish contact mine with one of her propellers without causing it to detonate; furthermore, her mining and torpedo operations in general proved to be equally futile.

The suggestion that the "Maine" was sunk by Cuban conspirators in the hope of embroiling the United States and Spain is disproved by the fact that it would be impossible to lay a large mine in the area over which the Maine would swing at her mooring and connect it with two independent observation stations on shore, without attracting public attention. The mine would have to be carried out on a lighter or vessel of considerable size, moored in place, and electric cables paid out from the mine to an observing station, which would itself have to be connected by telephone with another observing station, each station being equipped with instruments to determine the exact moment at which the "Maine" was floating above the mine. The attempt to anchor a floating contact mine would present almost equal probabilities of detection.

Lastly, it has been suggested that the entrance to the harbor may have been mined, and that one of the mines may have broken loose or dragged its mooring, and come in contact with the ship, which was located, we believe, not very far from the harbor entrance. The trouble with this theory is that contact mines would scarcely be placed in a waterway where ships were free to come and go, and that, if the mine had broken adrift and was floating at the surface, the incurved plating which the divers discovered would have been the side plating at the water line, and not that of the double bottom.

There remains then the theory that the "Maine" may have been destroyed by an internal explosion, presumably of the magazines; but this suggestion is strongly controverted by the testimony of Capt. Sigsbee before the board of inquiry, which showed that on the fatal night everything connected with the ship was perfectly normal. The guncotton was stowed aft under the cabin, as were the torpedo warheads. The gun cotton primers and detonators were aft in the captain's cabin, and no torpedo was fitted with a warhead at the time of the explosion. As to the magazines, they were on that night at the normal temperatures for a tropical climate. There was no loose powder in the magazines. The magazines had been subjected to the regular inspection, the doors locked, and the keys were in the captain's cabin (from which they were recovered after the ship sank) at the time of the explosion. The evidence on this point is strongly against the possibility of any malicious blowing up of the magazines.

There remains the theory of spontaneous combustion of the magazine powder. This is rendered unlikely by the fact that the gunpowder for the big guns was entirely of the brown prismatic type; which, as is well known, is one of the safest powders known, and is not subject to any chemical deterioration, such as occurs in the smokeless nitro-glycerin powders. Had the magazines that exploded contained big-gun charges of smokeless powder, it is conceivable that spontaneous combustion such as, a few years ago, destroyed the French battleship "Jena," might have wrecked the "Maine."

On the other hand, the evidence shows that there was a small arm ammunition locker forward, and that it contained a new supply of ammunition for small-arm and small rapid-fire guns. This was presumably of the smokeless variety, and this fact will naturally raise the question as to whether the mischief might have originated at this point.

A Record Aeroplane Tour

WHEN he alighted upon Governors Island at 2.38 o'clock in the afternoon of Friday, August 25th, Harry N. Atwood completed his long journey from Chicago in triumph and established a new record for long distance travelling by aeroplane. He started from St. Louis at 8.05 A.M., August 14th—12 days before—and, flying from 40 to 150 miles each day, he completed the 1,265-mile trip without difficulty or serious mishap. His journey is the longest ever made across country by aeroplane, and the first real pleasure tour. Atwood was able to fly every day, and each day he made headway, although on a few he was obliged to wait until late in the afternoon for the wind to die down. His longest day's flight was 286 miles made the first day and his shortest 27 miles made the last.

When he passed Rhinecliff, N. Y., at 8.39 A. M., the day before he finished, Atwood was 18 miles ahead of the long-distance record of 1,164 miles made in 80 days in a circuit race in Germany. The European circuit aeroplane race was only about 1,000 miles in length and it required nearly a week longer than the time required by Atwood. The circuit of Britain race, 1,060 miles in length, although completed by Lieut. Conneau and M. Vedrines, in three days, was only finished by Mr. Valentine, on a French monoplane, and Capt. Cody, in his huge British-built biplane, in 13 and 14 days respectively. Thus it can be seen that Atwood surpassed their performances despite the engine trouble which delayed him considerably during the last three days of his trip. At one time, while he was nearing Albany, he was obliged to alight and tighten the bolts which secured the engine to the frame of the aeroplane. In ten minutes he was *en route* again. After circling about the capital city of New York State he was compelled to descend at Castleton, a few miles further down the river, on account of the burning out of a bearing in the motor. After rebabbitting this bearing over night, he made a fine flight down the river, dipping suddenly and passing under the Poughkeepsie Bridge, and circling over the parade ground at West Point, but he did not land on the parade ground owing to his fear that he could not start from the field successfully because of the trees and buildings surrounding it. Instead he alighted high up on the other side of the river, at Garrisons, replenished his fuel, and started for New York. When at Nyack, a half hour later, the motor suddenly gave out and he was obliged to find a landing place quickly, as he was not at a very great elevation. Dexterously guiding his machine, he alighted on a narrow patch of open field between a barn and an apple orchard. The motor was repaired overnight, and the next day, despite the thorough soaking which the aeroplane received in a heavy rain the night before, Atwood was able to make the trip successfully under lowering skies and with a strong wind at his back. Under these weather conditions he was only 48 minutes in covering the 27 miles to Governor's Island.

The total flying time of the Burgess-Wright biplane used by Atwood was 28 hours and 31 minutes, which corresponds to an average speed of 44½ miles an hour throughout the long trip. The journey was accomplished in twenty flights of an average length of 68¼ miles. Every time the machine alighted and started again without mishap, and the fact that it was never damaged, even in the dangerous forced descent at Nyack, speaks well indeed for Atwood's skill as an aviator. His flight shows up well in comparison with the *London Daily Mail's* Circuit of Britain race and endurance test as, like the competitors in this English event, he did not change his engine or any essential part of the machine. Furthermore, he had several days of more difficult flying around the Great Lakes and above the Hudson, than was experienced by any of the aviators mentioned above in the British contest. While flying over the water was dangerous for Atwood, even with pontoons on his biplane, with a hydro-aeroplane such as Curtiss has devised, it would be preferable to follow rivers and canals, upon which a forced descent could always be made without danger.

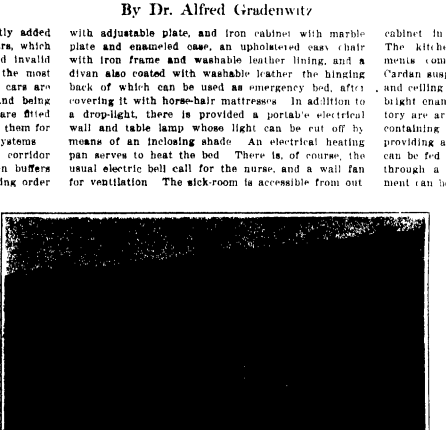
The successful termination at New York of Atwood's tour has shown America to still be in the lead as regards the practical use of the aeroplane for pleasure and touring purposes. While France has made a far greater use of it for military purposes, and England is taking it up for carrying of the mails, a young American with only a few months' experience in flying, has shown that it is possible to tour for pleasure and without danger in an American aeroplane, fitted with an American motor. The lesson taught by the motor troubles which he experienced is that for safety a touring aeroplane should be equipped with two separate engines, so that in case of failure of one, the other can be used. Mr. Edwin Gould foresaw this necessity two years ago and offered a generous prize of $15,000 through the SCIENTIFIC AMERICAN for a twin-motor aeroplane. Already one American monoplane has been built and flown with two motors, and several machines of this type, we understand, have also flown abroad. The Gould prize is still open for competition, and we hope that by July 4th of next year, at least half a score of aeroplanes will be built to compete for it.

Hospital Cars of the Swiss Federal Railways

Carrying the Sick by Rail

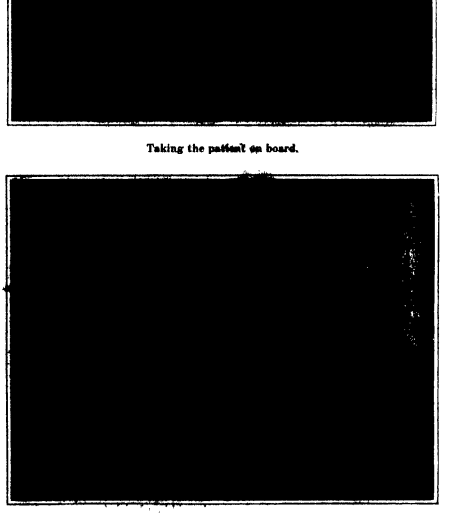
By Dr. Alfred Gradenwitz

THE Swiss Federal Railways have recently added to their rolling stock several hospital cars, which are intended for the conveyance of sick and invalid travelers, and whose equipment represents the most modern development in this direction. The cars are placed at the service of private parties, and being intended especially for long journeys, they are fitted out with all the technical equipment to adapt them for travel over the various European railway systems.



The hospital car is built as a four-axle corridor carriage with two bogies, its length between buffers being 63½ feet and its total weight in working order 41¼ tons. Not only is it fitted to travel on all standard-gage railway lines of the Continent, but it is designed also for transfer on the Scandinavian and Sicilian ferry-boats.

In addition to the brakes ordinarily in use on Swiss railway lines—namely, an automatical Westinghouse emergency brake with a braking cylinder of 8,800 pounds normal piston pressure, combined with a Westinghouse regulating brake there is provided a Hardy switching vacuum emergency brake with two cylinders of 3,080 pounds lighting power each, which are designed for automatic working as well as for direct manipulation. As French railways still use emergency chains for safety couplings—the hose couplings of the two Westinghouse brakes being located between the chains—three pairs of Westinghouse braking hose had to be arranged at each end of the wagon. The brake can also be controlled by means of a hand-wheel from each platform. In each compartment in the car and also in the passage, there is a safety brake, with one handle for actuating both the automatic Westinghouse brake with the signaling whistle and the electrical interconnection signal of the Paris-Orleans Railway or the automatical Hardy brake. In addition each wagon is fitted with the Prudhomme electrical interconnection signal of the French and Belgian Northern Railways, the alarm bell line of German Prussian and the holders for the alarm cord prescribed by Austrian railways. Ten signal holders of different designs had to be put in so as to comply with the special regulations of each of the railways on which the car is intended to travel.



The car is heated by steam circulating in smooth tube radiators with Wilheim regulators in general use on the Swiss Federal Railways. In order to insure a satisfactory gradation of heat, a radiator with Jenkins's regulating valve is provided in the sick-room. A hot air heating installation on the Pape-May system serves to heat up the car when stalled or before starting or when traveling lines not equipped with steam heating. All the various compartments of the car are electrically lighted on the Brown, Boveri & Co system the total candle-power being 272. The dynamo driven through belt transmission from one of the car axles in conjunction with eight accumulator batteries of 1,600 watt-hours each, also supplies electrical energy for various apparatus with which the car is equipped.

The sick-room, which is located in the middle of the carriage, and the adjoining lavatory, are fitted up aseptically in the same manner as up-to-date hospital rooms, all the walls, ceilings and floors, as well as the furniture, being readily washed and disinfected, while all the angles of the walls and ceiling are rounded off and any joints covered over with smooth nickel-plated metal rods. The walls and ceilings are painted with white enamel and simple decorative patterns. Extensive use has been made of glass, porcelain, marble and nickel-plated metal. The floors are fitted with inlaid linoleum.

The sick-room contains a good bed with iron frame and steel mattress and a removable nickel-plated lifting device. The horse-hair mattresses are made in three parts to facilitate disinfection; a chest of drawers fitted into the wall contains several changes of bed linen. The sick-room further contains a bed-table with adjustable plate, and iron cabinet with marble plate and enameled case, an upholstered easy chair with iron frame and washable leather lining, and a divan also coated with washable leather the hinging back of which can be used as emergency bed, after covering it with horse-hair mattresses. In addition to a drop-light, there is provided a portable electrical wall and table lamp whose light can be cut off by means of an inclosing shade. An electrical heating pan serves to heat the bed. There is, of course, the usual electric bell call for the nurse, and a wall fan for ventilation. The sick-room is accessible from out side through broad folding doors in the side-walls, through which the invalid can be brought in on a stretcher or Sedan chair.

Taking the patient on board.

The sick-room of the hospital car.

Adjoining the sick-room are the quarters for the attending physician or nurse. The furnishings here include sleeping accommodation and an upholstered seat coated with washable leather, further a folding table and a metal and plate glass cabinet for medicines surgical instruments dressing, etc.

A first-class compartment for the patient's relatives or friends is attached, this also being equipped as a "wieeper."

The seats are lined with bright gray cloth to match the carpet. All metal parts throughout the carriage are nickel-plated.

The kitchen is equipped with an ice-box for food and drink and to store ice for medical use; there is a marble topped table and a fire-clay sink on nickel brackets with self-locking water faucet. Under the kitchen table there is a small chest of drawers for polishing utensils and on top of the ice box a crockery cabinet in which the kitchen linen is also kept. The kitchen is operated electrically, its arrangements comprising two quick-acting radiators with Cardan suspension and a toasting pan. Both the wall and ceiling are lined with slate iron and painted with bright enamel. Over the kitchen as well as the lavatory are arranged water tanks of tinned copper plate, containing a total of about 1,000 liters of water, thus providing an ample water supply. These water tanks can be fed directly from the roof or from underneath through a pressure conduit. The baggage compartment can be heated and contains a folding bench for domestics. A special lavatory is provided for general use. The passage also contains an upholstered hinging seat for domestics.

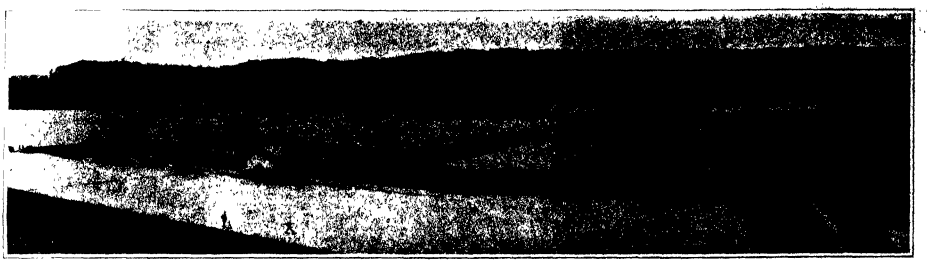
All the sliding doors of the carriage run on ball bearings.

Four carriages of this type, constructed by the Schweizerische Industrie-Gesellschaft of Neuhausen, have so far been placed on the tracks.

The Completion of Hann's "Climatology"

HOFRATH Prof. Dr. Julius von Hann, the venerable and venerated Austrian meteorologist, has just published the third and final volume of a revised and greatly enlarged edition of his "Handbuch der Klimatologie." The first edition appeared in 1883, the second in 1897, and the first volume of the third edition, just completed, in 1908.

Although dealing with a subject of universal interest, viz. the climates of all parts of the world, this work has for many years enjoyed the position of being sui generis. Since the appearance of Woeikow's "Klimate der Erde," in 1887, no other work discussing this subject in detail has appeared, in any language. The climatologists of the world appear to have recognized that Hann was better able than any one else to handle the subject adequately and have left him the undisputed master of the field. His manner is encyclopedic. Reading omnivorously and writing with unflagging industry in spite of advancing years, he has produced a digest of nearly all the existing literature of climatology and climatography, a fitting companion piece of his "Lehrbuch der Meteorologie" published in 1901 and in a more condensed form in 1906. The "Klimatologie" like the "Meteorologie" is however more than a digest. It is also an indispensable bibliography, as it contains thousands of references to the literature on which it is based. Moreover those references are not confined to scientific literature; popular books of travel for example have been laid under heavy contribution.



An English version of Hann's unique work is sorely needed. In 1903 Prof. Ward, of Harvard, published an admirable translation of the first volume of the second edition, but this deals only with climatology in general not with the climates of particular countries.

Niagara and Victoria

WHAT is the true comparison between the power of Niagara and the Victoria Falls in South Africa?

The answer is that the flow at Niagara varies between 62,000,000 and 161,000,000 gallons per minute, that at Victoria is as low as about 5,000,000 gallons in August.

The mean available drop at Niagara is 160 feet and at Victoria 380 feet. Hence, while the maximum Niagara flow represents about 3,000,000 horse-power, the Victoria flow in August represents only 580,000 horse-power, and, accepting the statements of local authorities that in November the flow at Victoria drops to only 2,500,000 gallons per minute the minimum horse-power there can be only about one-tenth of Niagara's minimum. The maximum of Victoria is not given.

Bird's eye view of the Fernbank dam just opened in the Ohio river near Cincinnati.

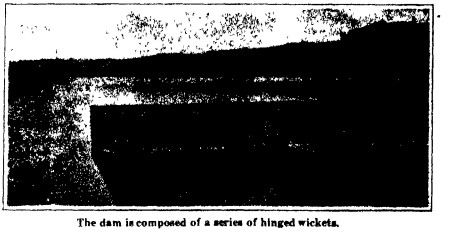
The Largest Movable Wicket Dam

Providing a Nine-foot Boating Stage of Water in the Ohio River

THE largest movable wicket dam in the world and the only one built entirely of concrete and steel has just been opened for business in the Ohio River near Cincinnati.

When the steamboat "Indiana" passed through the lock on July 25th, as here shown, the event marked the completion of a six years' task in building one of the most remarkable dams, indeed, the only structure of its kind. No other dam is built entirely from concrete and steel.

There are 60,000 cubic feet of concrete in the structure, of which 35,000 feet is under water and cannot be seen at any time. All the gravel, sand and crushed stone used in this vast amount of concrete was excavated on the site of the big dam when dredges scooped out the river's sandy bottom down to bed rock where all concrete footings are planted.



The foundation for the dam proper, extending across the river is of concrete and steel and arranged so that the movable wickets work independently of each other and may be removed like so many pegs from so many holes. The one illustration shows the government dredge boat beginning to stand the wickets in place in their sockets on the bed of the river. The long line of wickets forms the dam to hold back the water. The mechanism of the dam allows these movable wickets to be dropped flat upon the bottom of the river bed or raised at will by means of compressed air. These movements are controlled from the Ohio shore.

The working of the dam proper regulates the height of water in the 25 mile pool above it. When the river is high and there is no need of the artificial stage of water the wickets are lowered flat on the bed of the river and craft pass over as if no dam were there, but when the water is low and the stage of water is artificially formed above the dam the craft must pass through the lock on the Ohio shore from the higher or lower stage, or from the lower to the higher, according to the direction in which the boats are traveling, as illustrated in the photograph showing the steamer "Indiana" passing up stream through the lock canal along the Ohio shore. The government has appointed four lock keepers to transfer these boats through the big dam. These men work in shifts.

That the big Fernbank dam, known officially as No. 37, is a big success may be gleaned from the fact that the United States government will build others like it in the Ohio River to make that stream navigable the year round from Pittsburg to Cairo, a distance of more than a thousand miles. It is a step completed to establish a permanent stage of not less than nine feet of water in the Ohio River the year round. This dam located at Fernbank, Ohio, twelve miles below Cincinnati, will give Cincinnati a permanent minimum stage of nine feet of water for a distance of 25 miles. It cost the government $1,500,000. Early in September people of the Ohio Valley will gather in Cincinnati and the structure will be officially dedicated.

How the water pours through the Fernbank dam.

The dam is composed of a series of hinged wickets.

The Pebble Industry

A PECULIAR form of mineral wealth is found on Plum Island and Goose Island, two of a row of islands lying between the northern point of Long Island and Watch Hill. It consists in heaps of richly-colored quartz pebbles, showing red, yellow, purple, and other hues, which are locally called agates. They are used in making stained-glass windows, and there is a sufficient demand for them in New York to keep the owners of one or two sloops employed in gathering them from the beaches, where the waves continually roll and polish them, bringing out the beauty of their colors.

The gate is mounted on wheels like a freight car on a track like that of a railroad.

Government dredge setting the wickets in place.

THE LARGEST MOVABLE WICKET DAM

The Isolation of an Ion

Measuring the Smallest Thing in the World

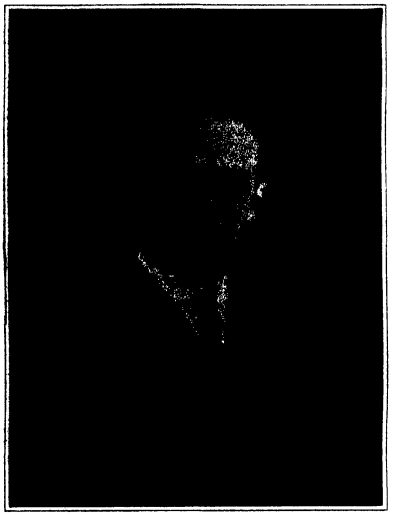
By William J. Humphreys, U. S. Weather Bureau

JUST as the accurate measurements of controlled phenomena have taught us much that is definite and much that is useful about the divisibility of matter, so also cleverly designed and skillfully executed experiments are giving us equally definite knowledge of the atomic nature of electricity, of the fact that there is a measurable and seemingly ultimate limit to the divisibility of an electric charge, and what the exact magnitude of the ultimate charge is

Like nearly every other discovery of importance, this one, too, has a long and an honorable history. In fact it can be traced back, step by step, almost a century.

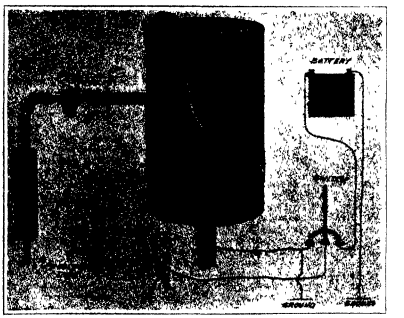
The first, and in many ways most fruitful contribution to this subject, was made by that prince of experimenters, Michael Faraday. It consisted in proving that when an electric current is passed through a water solution of any one of certain substances, the substance itself is taken out of the solution, to an extent dependent entirely upon the quantity of electricity so passed, and upon the nature of the substance dissolved. Thus, when the same current is passed in series through the water solutions of several salts, such as sodium chloride, silver nitrate, copper sulphate, and the like, the weight of the metal deposited, or, under proper conditions, permanently removed from the solution, is directly proportional to the atomic weight of the metal itself, and inversely proportional to its valency, that is to say, to the number of hydrogen atoms necessary chemically to take the place of one atom of the metal. This proportionality between the quantity of electricity passed through the solution, and the resulting amount of chemical decomposition, holds rigidly true, within the limits of experimental error, under all conditions, and hence it seems practically certain that to each ion in a solution conveying an electric current there belongs a definite electrical charge, and that the smallest of such charges is that carried by a single hydrogen atom, or by a single atom of any other univalent substance. A bivalent atom, such as copper in copper sulphate, carries just twice the smallest, or univalent charge, a trivalent atom three times the smallest charge; and so on for atoms of still higher valency. Hence, in electrolytic solutions there is a measurable "smallest possible charge," of which large electrolytic charges are only definite multiples.

A natural inference from these experimental facts would be (and this inference was drawn by many) that electrical charges are just as definitely atomic in their nature as, for instance, is a mass of iron. That just as, under given conditions, there is a limit to the actual, though not to the conceivable divisibility of matter, so too there is a limit to the actual, though again not to the conceivable divisibility of an electric charge. This, however, was only an inference, and for many years the way to test it, in the case of any quantity of electricity other than that used in the decomposition of an electrolyte, was not evident. Besides, even in the process of electrolysis, the most refined measurements could directly detect nothing less than the aggregate of countless millions of elementary charges, so that the value of the unit charge was only inferentially and not immediately determinable.



About a dozen years ago, J. J. Thomson, H. A. Wilson, and C. T. R. Wilson began, in the Cavendish laboratory at Cambridge, England, a series of most ingeniously devised and skilfully executed experiments that proved the existence of minute electrical charges in conducting gases, and showed their average value to be, as nearly as could be determined, the same as that of the electrolytic charge spoken of above.

C. T. R. Wilson showed that a fog of water particles will form in dust-free air whenever the degree of super-saturation is sufficiently pronounced. If the air is ionised, or has been rendered conducting through the action of X-rays, or otherwise, then a four-fold super-saturation causes condensation of the water vapor on the negative electrons; a six-fold super-saturation gives condensation on the positive electrons, and an eight-fold on the neutral molecules of the gas itself.



Now, a knowledge of the amount of water vapor present, and of the extent of the cooling below the dew point by which the super-saturation is produced enables one easily to compute the weight of the water condensed as fog. Furthermore, if the fog is left to itself, it slowly settles at a rate which, as Stokes proved long ago, depends upon the size of the individual particles and upon the viscosity of the medium through which they fall.

A measurement, then, of the rate at which the fog falls, since it all falls at about the same rate, enables one to calculate the size of the individual particle, and this knowledge of the size of the particle, together with a knowledge of the amount of water condensed, at once gives the total number of particles.

On bringing a charged body near this electrified fog its motion is modified, and a means is at hand for measuring the magnitude of the charge on each particle.

Prof. R. A. Millikan, who has isolated an ion and measured the ultimate unit of electric charge.

The apparatus by means of which Prof. Millikan has isolated an ion and measured its charge

Probably the simplest method of measuring this charge, through the behavior of the fog as a whole, is that devised by H. A. Wilson. The rate of fall of the fog is measured when there is no external electric field acting on it, and thus the size and weight of the individual particle determined. After this a vertically directed uniform electric field is brought to bear on the particles, and regulated to just counteract the force of gravity, so that the fog neither rises nor falls. Under these conditions of equilibrium the value of the charge on each particle of fog, multiplied by the strength of the field, is equal to the weight of the suspended particle; and hence when both the weight of the droplet and the strength of the field that keeps it in suspension are known the numerical value of the charge is also known.

All this, however, assumes that the rate of fall of the fog en masse, the group rate, is the same as would be that of a single one of its droplets if alone. This as a matter of fact is not rigidly true.

For this and for other reasons it seemed extremely desirable to Prof. R. A. Millikan of the Ryerson physical laboratory at the University of Chicago somehow to isolate and to measure an ion entirely by itself.

A few years ago it would have been almost silly even to have dreamed of accomplishing such an experimental feat. But Prof. Millikan has most cleverly solved this seemingly impossible problem, and by so doing probably has made by far the most accurate of all determinations of the value of this fundamental unit, the atom of electricity. Nor is this all, for the improved value of this unit carries with it correspondingly corrected values of other things such as the number of atoms per unit weight of any given element and the mass of the individual atom itself.

The full account of this ingenious and valuable investigation is given in the *Physical Review* for April of this year, and should be consulted by any one especially interested in the subject. In brief the process by which single ions were isolated and individually measured was as follows.

A fine spray of oil was blown by dust-free air into a dust-free chamber, the bottom of which was closed by a brass disk 22 centimeters in diameter. The center of this disk, which was perfectly plane on the under side, was pierced by a pin-hole through which an occasional oil droplet fell. Strictly parallel to this disk, and just 16 millimeters below it, was another brass disk of the same size. A band of thin ebonite was bound around the edges of the disks, while ebonite rods kept them fixed in position and also strictly insulated from each other. In this way a cylindrical air chamber 22 centimeters in diameter and 16 millimeters long was formed between the two parallel brass plates.

A parallel beam of light was passed through two diametrically opposite glass covered holes in the ebonite band, and hence immediately beneath the pin-hole in the upper plate. Through a third glass covered hole in the ebonite band a low power telescope was so focused as to show distinctly any object floating in the air immediately beneath the pin-hole. As soon as one or two droplets chanced to fall through this opening, and, therefore, into the field of the telescope, I was closed by an electromagnetically operated cover, so as to prevent, as far as possible, all disturbances due to air currents. Changes in the size of the drop were at most entirely eliminated by the use of substance that evaporate slowly, and by the additional precaution of having the volume of the cylinder through moistening its walls, already saturated with the vapor of the substance used.

The rate of fall of the droplet due to the force of gravity alone, was measured and in the way its size and mass approximately determined, as above explained. The plates were then charged to a known difference of electrical potential and hence the move

ment of the droplet if electrified, was changed The new velocity was measured and its direction noted These measurements with the electric field alternately off and on were repeatedly taken, but during the course of the observations it frequently happened that the droplet encountered and entrapped a free ion of one or the other sign, as was evidenced through its abrupt changes in velocity The more ionized the gas the more frequent the captures

By this process free gaseous ions of either sign have been captured at will, either singly or in multiples, and their magnitude has been so carefully measured, under conditions so free from assumptions, that the size of the electrical atom, the smallest quantity of electricity now attainable, is known probably to within one part in 500 of its actual value

Numerically this value is the absolute electrostatic unit multiplied by 4.891×10^{-10}, a quantity incomprehensively small To illustrate its excessive minuteness, let us suppose one hundred millions of people should begin to collect and count these atoms of electricity, just as Prof. Millikan has collected and counted them, only at the extraordinary rate of 100 every minute, and let them keep steadily at it until they had enough to generate by electrolysis sufficient hydrogen to fill a child's toy balloon of some eight inches diameter. Certainly this would not be enough electricity to consider in any commercial transaction, and yet it would take the above hundred million hustlers geological ages—in fact something like four millions of years—to collect it by the process described. Surely, then, the electric ion is small beyond comprehension, and its definite isolation and exact measurement stands forth as one of the cleverest, as it is also one of the most important, achievements of modern physics.

The Right and the Wrong Way of Mining Coal

To the Editor of the SCIENTIFIC AMERICAN:

Dr Holmes's article upon the conservation of the coal resources was highly interesting, and from the viewpoint of the scientist leaves nothing to be desired It was, to my mind, the distinctive feature of your issue of August 12th, 1911 With your permission I would like to state a mere layman's side of coal conservation

To clearly convey my meaning I will use two mines about 900 miles apart The Blossburg Pa., coal region has five veins of coal, that of the Sullivan County, Indiana, region has seven veins of coal Now note the difference between mining systems

The lower drift at Arnot, Pa., has been worked since 1866 There was seldom less than 800 miners employed in it The workings extend over 22,000 acres and 96 per cent of the coal is taken from the workings In the forty-five years the mine has been worked but six men have lost their lives while digging coal, and an accident is a very rare occurrence That I term the correct method of working a coal mine

In Sullivan, Indiana, a coal mine has been worked seventeen years About 150 miners are employed The workings extend over 600 acres An average of seven men have been killed in it each year, while accidents are of almost daily occurrence That I call the incorrect method, for less than 60 per cent of the coal is taken out

The method of working at Arnot, Pa., is this All coal is both undercut and sheared by pick or machine, then a few ounces of powder brings down the coal without shattering the strata above, so that when the out-crop is reached the pillars can be drawn, thus leaving but three or four per cent of the coal behind

The freedom from death and accident is due to this. When the miner reaches his room he immediately takes his lamp from his head and cautiously raises it once in a while to see if the flame will denote the presence of fire damp If so he does not blow it out, but slowly puts it down on the ground and extinguishes the lamp by placing his coat over it When the miner reaches the "face" he takes a pick and sounds the roof to find out if there is any loose rock overhead If so, he either wedges it down or sets a prop under it Though the mine is full of coal dust no dust explosion ever took place in it

At Sullivan, Indiana the coal is "shot from the solid" Little or no undercutting is done Each miner uses at from five to ten pounds of dynamite or an equally strong explosive each day This not only loosens the coal, but shatters the roof also, so that if a vein of coal is above the one worked it is extra hazardous It does more It causes the almost daily accident and the loss of about 40 per cent of the coal in the mine It is rarely possible there to draw the pillars So the net result is the loss of 40 per cent of the mine worked the almost entire loss of the vein above and a continuous maiming and killing of the miners

Consider this matter in another way Supposing a half ton or more of dynamite were exploded in five and ten-pound charges in the streets of a city within one hour What would be its effects in the open? Apply this, then, to what must be the effect of the explosion of a similar amount in a mine where the effect of the explosion has but a single direction to expand. All this is to take place within the area of fifty acres

The method used in Indiana is in vogue all over the West It is wasting, criminally wasting, a large percentage of the most valuable of nature's gifts and causing a wholesale slaughter of men I edited the national official organ of the coal miners for seven years, and my observations extending practically all over the coal fields, taught me that there was but one way to prevent the slaughter of miners and the criminal waste of coal, to wit: To make it a penal offense to shoot coal from the solid or to attempt to get it without undercutting and shearing the "shot" with either pick or machine.

What would be the result? But one-tenth of the powder would do the work; there would be no dust explosions, for little dust would be made, the strata above would be practically unharmed, thus preventing the killing and maiming of miners and securing over 90 per cent of the coal.

That this is so is again illustrated by coal regions separated only by county lines, Allegany County, Maryland, where the method used is similar to that used in Arnot, Pa., with similar results, and Allegheny County, Pa., where the Indiana method is used and the same results ensuing.

When I stated these things in the miners' organ the operator would sneer at them because he wanted to get the greatest amount in the shortest time regardless of the wrong he was doing to the country and the injury to future generations Many miners indulged in somewhat heated criticisms of myself, for they, too, wanted to get the most for the least

Some day, some time, we will secure a legislator and a Congress with patriotism and courage enough to enact laws that will stop this devastation and the destruction of an asset incalculable in value

Blossburg, Tioga County, Pa. S M SEXTON.

Eugenics and the Conservation of Humanity

To the Editor of the SCIENTIFIC AMERICAN:

Conservation of American forests is important. So is conservation of American coal, and oil, and natural gas, and water supply, and fisheries But the conservation and improvement of the American race is far more important than all other conservation The real wealth of a nation is the quality of its people Of what value are endless acres of forests, millions of tons of coal, and billions of gallons of water, if the race is not virile, and sane and sound? You have shown a fine discrimination in including an excellent editorial on eugenics in your Conservation Number, and as one of your many readers I wish to thank you heartily for it Germany is ahead of us in her forest policy She is also ahead of us in her efforts to improve and conserve her people England is ahead of us, too, in the practical interest which is now taken there in the splendid work of the National Eugenics Laboratory of the University of London, and of the Eugenics Education Society. In the United States we are just beginning to take notice of the work of foreign investigators along eugenic lines, and slowly but surely the painstaking researches of Dr. Charles B Davenport, and of his colleagues of the Committee on Eugenics of the American Breeders' Association, are attracting attention and will lead to action.

Fearfully misguided has been most of our so-called philanthropy We have housed and clothed and fed the defective, the degenerate, the delinquent, to such an extent that we have encouraged them to reproduce their kind in ever-growing numbers. We have spent increasing sums for asylums, almshouses, prisons and hospitals, in which we have *temporarily* confined the insane, the pauper, the habitual criminal, the imbecile, leaving them free, during most of their lives, to propagate their kind It is a fact, disguise it as we will, that we have taxed ourselves to support institutions which have resulted in increasing, and not decreasing, the number of the unfit. We have before us an immediate duty, of tremendous importance, in caring for our own unfit; in seeing to it, by adequate legislation, that the insane, the habitual criminal, the feeble-minded and similar classes are *permanently* segregated, so that they cannot reproduce their kind to be a further burden upon the nation, and in enacting laws which shall prevent the marriage of those whose offspring will be unfit.

But, in addition to our own very heavy burden of those who are defective or degenerate, we are adding every year, by immigration, many hundreds if not thousands of aliens whose presence here will inevitably result, because of their own defects, or those of their offspring, in lowering the physical and mental and moral standards of the American race. We, in the United States, have a wonderful opportunity to apply eugenic principles, upon a scale which no other nation can begin to approach, in our power to select and regulate alien immigration. Unprejudiced experts are agreed that our present very liberal immigration laws do not suffice to preserve the *status quo*—physical and mental—of our population, and are very far indeed from promoting any improvement We are here forming a new race, extraordinarily heterogeneous in character, yet we are to-day taking more care to see that a Hereford bull or a Southdown ewe, imported for breeding purposes, are sound and free from disease than we take in seeing that the alien fathers and mothers of future American children are sound and strong and sane and fit Biologists admit that they have much to learn about heredity But of some things they are already sure. Enough is known to make it absolutely essential, if the quality of the American race is to be preserved, that there should be a far more careful selection of our incoming alien immigrants, on eugenic grounds, than we have ever attempted

The need is imperative for applying eugenic principles in much of our legislation But the greatest, the most logical, the most effective step that we can take is to begin with a proper eugenic selection of the incoming alien millions If we, in our generation, take these steps we shall earn the gratitude of millions of those who will come after us, for we shall have begun the real conservation of the American race

Silver Lake, N H. ROBERT DEC WARD.

Education and Success

To the Editor of the SCIENTIFIC AMERICAN:

Your article on the above subject in the issue of June 3rd appeared to me most admirable, and the conclusion that "your success is measured not by what the world gives to you, but by what you give to the world," one to be written in letters of gold

But is not the chief object of each one of us personal happiness? And how is the question affected when we consider personal happiness? Who are the happiest of human beings? After a long life, in which I have met and consorted with all sorts and conditions of men, I cannot help thinking that what Greville recorded—I write from memory—nearly one hundred years ago is true The men who pass their lives absorbed in personal ambition, personal aggrandizement, or personal pleasure, are *not* happy Those who live for others or seek their highest personal manifestation in labors to advance art, science, literature, and morality are happy.

If, then, the greatest success man can attain on earth is personal happiness, we again find that *"your success is measured not by what the world gives you, but by what you give the world."*

Wick Court, near Bristol, England

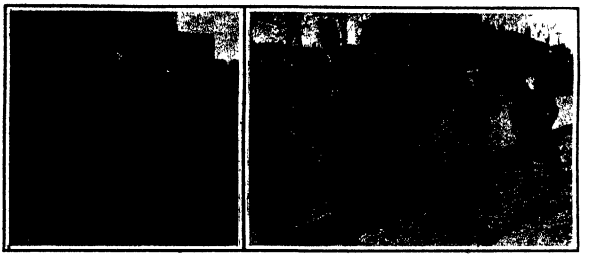
Preservation of Niagara Falls

To the Editor of the SCIENTIFIC AMERICAN:

I take this occasion to compliment you upon your strong editorial stand for the preservation of Niagara Falls. Though everyone knows that the SCIENTIFIC AMERICAN is published for the scientific and the industrial arts, it is certainly refreshing to see a journal of your class have some feeling and regard for America's natural wonders.

These wonders, and particularly Niagara Falls, are national assets in more senses than one, because they draw together citizens from all parts of the country, and they also amass great wealth in the form of visitors to the localities possessing these wonders.

Therefore the wonders of America should be preserved, not only for sentimental reasons for all lovers of the beautiful, but also for the patriotic and financial reasons.



I trust that the SCIENTIFIC AMERICAN may be successful in its good work in stopping any further encroachments upon what is left of the beauty of Niagara Falls.

New York City. PALMER H. LANGDON.

Curiosities of Science and Invention

Track Inspector's Bicycle

IN order to lighten the work of the plodding trackwalker a French inventor has designed an attachment for a bicycle which will permit the machine to travel on the rails, thereby allowing the man who inspects the track and roadbed to cover a larger territory in a given time and with much less fatigue. The attachment is shown in the accompanying engravings. It consists of a pair of supplementary forks secured to the main forks of the front wheel and provided at their lower extremities with rollers adapted to bear on opposite sides of the rail. In addition to this there is a light steel frame secured to the main bicycle at the rear which carries at its outer end a small roller that rides on the opposite rail of the track. This serves to keep the two wheels of the bicycle on the rail without any effort of steering on the part of the rider. In order to permit the rider to preserve a comfortable position when traveling slowly around a curve that is steeply banked, the roller is made adjustable under control of a small hand wheel, whereby it may be thrown in or out so that the rider can adjust himself as nearly as he desires to the perpendicular. The roller frame may be detached at a moment's notice and secured to the bicycle in the manner illustrated, and the supplementary forks may be raised, permitting the wheel to be ridden over an ordinary road.

Fitted for road travel. In use on a railroad Track.

A track inspector's bicycle.

A Curious Indian Cantilever Bridge

SOME interesting examples of Indian ingenuity are afforded on the River Skeena and its tributaries in north British Columbia. These waterways in their upper reaches flow very swiftly and for the most part through deep ravines. As it is impossible for the Indians to cross them by means of canoes, they have resorted to bridging. Their bridges are interesting structures from the engineering point of view, inasmuch as the cantilever principle is adopted. The bridge of this design shown in the accompanying illustration spans the Bulkeley River where it is about 120 feet wide, and the height from the bridge to water level is about 80 feet.

It is built of wooden logs, the legs of the structure being formed of single stout logs varying from 60 to 80 feet in length. The task of lowering them into position must have demanded considerable ingenuity on the part of the builders. They are buried about 15 feet at their lower ends, and anchored by the superimposition of masses of large rock rolled and carried to the site. The longitudinal members of the shore spans are similarly buried in the ground and lashed to the ends of the diagonal legs. These main members, corresponding to deck girders, are about 120 feet in length, and to either end the A members of the superstructure are lashed. Elaborate cross bracing is resorted to in order to secure greater strength.

When the bridge was first erected the different members were simply secured together by willow thongs, but when the British Columbian government erected a more substantial suspension bridge lower down the river, the Indians assembled and followed the white man's operations with great interest. They observed how the thick wire cables were slung and anchored, and accordingly decided to introduce wire into their own structure. They procured the material for this purpose from wherever they could and introduced it in a most fantastic manner. Also when the Grand Trunk Pacific Railway engineers commenced working on their track near by the Indians procured odds and ends such as bolts and spikes from them for introduction in their bridge so that now it is a strange looking piece of work, though the fundamental cantilever lines are still distinct.

Cantilever bridge built by Indians in British Columbia.

A giant induction coil discharging across a four-foot gap.

A Giant Induction Coil

THE accompanying engraving illustrates one of the most powerful induction coils in existence, viz., a mammoth apparatus 125 centimeters (49.2 inches) in spark length, constructed for the Vienna Technical High School. A similar apparatus has been constructed for the Potsdam Astrophysical Observatory, both being warranted to stand a potential of 1,000,000 volts.

The discharges of these induction coils comprise the fundamental and upper harmonic vibrations, the minimum and maximum wave lengths being inferred approximately from the length of wire in the primary and secondary circuits respectively. In connection with these giant induction coils the wave length of the fundamental vibrations is about 300 kilometers (186 miles) and that of the highest upper harmonic about 100 meters (328 feet). Their construction is based upon the following voltages between a positive point and negative plate with different distances at the moment of the first spark passage:

Spark length (cms.)	1	2	5	10	20	30	40	50	60
Voltage	50	100	175	275	475	650	800	950	1100

Spark length (cms.)	70	80	90	100
Voltage	1250	1400	1550	1700

On account of the special winding method contiguous turns of a coil will readily stand a much higher voltage so that their efficiency owing to the much smaller self-induction is increased considerably, resulting in those wonderful remarkably sustained discharges which sometimes show the aspect of flames. In fact the discharges of these giant induction coils carry a considerable amount of electricity.

The Heavens in September 1911

The Comets in the Sky; Location of the Brightest Stars; the Planets

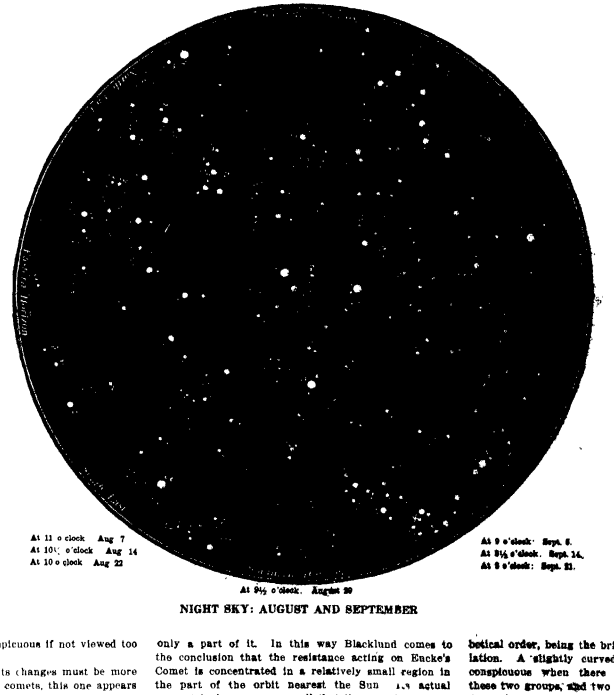
By Henry Norris Russell, Ph.D., Professor of Astronomy in Princeton University

HAD the Moon been in her first quarter, instead of her third, Kiess's comet, which was within twenty million miles of the Earth on August 16th, would have been fairly conspicuous to the naked eye. As it was, the moonlight drowned it out pretty thoroughly. By the beginning of September this comet's rapid motion carries it into 52 degrees south declination, making it quite invisible in our latitude. As it is rapidly receding from the Sun, and still faster from the Earth (owing to its retrograde orbital motion), it will doubtless soon disappear from the gaze even of southern observers.

Brooks's comet—discovered at Geneva, N. Y., on July 26th by a veteran observer of such bodies—is approaching the Sun, and will not be in perihelion until October 27th. During the early part of September it will be fairly near the Earth (some fifty million miles away) and will be high in the northern sky, and above the horizon most of the night during which time it will be favorably located for observation and may even be visible to the naked eye.

Still a third comet is now in sight—Encke's, which is noteworthy for several reasons. Firstly, it has the shortest period of any known comet, returning to the Sun at intervals of slightly less than three and one-third years. Secondly, it varies in brightness at successive returns in a very singular manner, being sometimes easily visible in small telescopes (as it is reported at the present return), while at other times, though equally near the Earth and Sun and apparently as favorably placed, it is excessively faint, and can only be observed with powerful telescopes, as was the case at its last return in 1908.

Prof. Blacklund of Pulkowa, Russia, who has spent much time in the study of this comet, finds that it always appears faint when it lies in certain directions from the Earth and Sun, behaving as if it was a thin flat disk, almost vanishing when seen edgewise, but fairly conspicuous if not viewed too obliquely.



The actual explanation of its changes must be more complete for, like other faint comets, this one appears as a roundish mass of light. It would be possible to explain the facts by assuming that the comet was composed of a great number of separate particles all *strongly flattened parallel to the same plane*, but some less artificial explanation will doubtless in time be available. Third among the peculiarities of this comet, and most interesting of all from the theoretical standpoint, is the fact that its period of revolution is decreasing. This proves that some force, other than the attraction of the Sun, must act upon it, for otherwise, like the planets, it would always take exactly the same time to complete a circuit of its orbit. The attraction of the planets themselves would indeed give rise to slight differences in the duration of successive revolutions; but when the laborious calculations necessary to determine these "perturbations" have been carried out and checked so as to exclude any chance of error, it is found that there remains an unexplained shortening of the comet's period.

It is one of the apparent paradoxes of theoretical astronomy that the return of a comet *earlier* than the predicted time (provided this can be accurately determined) means that some force has been at work which has *retarded* the comet's motion. A full explanation cannot be given by elementary methods; but the principle involved is this. The retarding force decreases the rate of the comet's motion, as might be expected; but the Sun's attraction acting on the now slower moving comet draws it into an orbit smaller than before—so much smaller, indeed, that even at the slower speed it gets round it in less time than formerly.

By refined methods, taking into account the change in the form of the orbit, as well as the period, it is possible to discriminate between the influence of a minute retarding force acting steadily all along the comet's orbit, and a more powerful one exerted along only a part of it. In this way Blacklund comes to the conclusion that the resistance acting on Encke's Comet is concentrated in a relatively small region in the part of the orbit nearest the Sun. Its actual amount is, however, so small that the retardation cannot be detected by direct observation immediately after the comet leaves this region. It is only at the following return when the cumulative results during the whole following period become evident, that the extent to which the comet has been retarded can be calculated.

Still another curious circumstance must be mentioned. The amount of the retardation is not always the same. In the middle of the last century the period was shortened by about two and a half hours in each revolution; but since then the influence was twice abruptly diminished. Prof. Blacklund is inclined to explain this by supposing that the comet's motion is hindered by passing through a cloud of meteorities—or something of that sort—which is not of the same density at the successive times when the comet strikes it.

Enough has been said to show what an interesting body this little comet is to the astronomer. Accurate observations are now secured for as long an interval as possible at each return, and great mathematical skill, and enormous labor in computation, expended in the calculation of its motion; but it may still be long before the nature, and especially the variations, of the strange resistance to which its motion is subjected are fully comprehended.

NIGHT SKY: AUGUST AND SEPTEMBER

The Heavens.

Turning now to our map of the evening skies, we find that the splendid Cygnus right overhead. To the west is Lyra, with the resplendent star Vega, and southward shines the less luminous Altair. A brilliant region of the Milky Way, below this, leads us to Sagittarius and Scorpio—the latter almost setting in the southwest. Ophiucus and Serpens are farther to the right; then Hercules, Corona and Boötes, in an almost vertical line below Lyra. The Great Bear is well down in the northwest, with the Dragon and the Little Bear above. The vacant region below the pole on the other side contains the modern constellation Camelopardus—made to fill a gap between the ancient ones. Farther to the right, in the Milky Way, is another fine series of star groups—Auriga, just rising, then Perseus, next Cassiopeia, with the less brilliant Cepheus between her and Cygnus.

The great square of Pegasus is well up in the east. Andromeda is on the left, and Aries below. A few stars of Cetus have risen to the south of east. About southeast is a bright star, which from its southern declination and isolation is at once recognizable as Fomalhaut, the only conspicuous member of the constellation of the Southern Fish. Above this is Aquarius and farther to the right Capricornus.

Though one of the fainter zodiacal constellations this last is a fairly definite group of stars, and can easily be made out on a clear night.

Its principal stars which bear the Greek letters Alpha and Beta, are close together in the northwestern part of the constellation, at the head of the Sea-Goat, as our initial shows. About 20 degrees to the eastward the monster's tail is marked by the stars Gamma and Delta Capricorni, the latter, though fourth in alphabetical order, being the brightest in the whole constellation. A slightly curved line of faint stars, only conspicuous when there is no moonlight, connects these two groups, and two similar lines run downward from them, forming a triangle whose third vertex is marked by two stars (in the Goat's fore paws) which, though not much fainter than those already mentioned bear the last letters of the Greek alphabet—Psi and Omega.

Alpha Capricorni is a fine naked-eye double star, with components 6¼ minutes of arc apart. Beta Capricorni is also a wide double, but as the components are very unequal in brightness and separated by but 3½ minutes of arc, the aid of a field-glass is needed to see them separately.

The Planets.

Mercury is evening star at the beginning of the month, but is too near the Sun to be seen. On the 9th he passes through conjunction, and thereafter is a morning star, reaching his greatest western elongation on the 23rd. About this time he rises at 4:30 A. M. and can easily be seen.

Venus is also in conjunction with the Sun on the 18th and changes from evening to morning star. She can only be well seen toward the end of the month.

Meteor Trains

IN the *Popular Science Monthly*, August, 1911, Prof. C. C. Trowbridge, of Columbia University, presents a summary of the results thus far obtained in his study of meteor trains, which he has now carried on for a number of years, and which he has made the subject of several earlier contributions to the scientific journals. His activity in this field of research has been recognised by the National Academy of Sciences, which has made him a grant from the J Lawrence Smith Fund, to enable him to extend his work in this direction

Prof. Trowbridge applies the term "persistent train" to a meteor trail of long duration—from several minutes to an hour or more—as distinguished from a trail lasting, at most, a second or two, such as is ordinarily seen in the wake of a meteor. A large number of these persistent trains have now been observed and measured, and their altitudes have in many cases been determined by simultaneous observations at two or more stations. They average about ten miles in length. They are at first straight narrow streaks, but gradually expand to a width of a mile, and become curved and twisted into various shapes, as they are drifted by the wind. These transformations are illustrated in the accompanying drawing. *A* shows the appearance of a train a few seconds after the nucleus of the meteor had disappeared. Soon after its appearance the train was sixteen to eighteen miles in length and at an altitude of fifty-six miles above the earth, as determined by triangulation from Sidmouth and Cardiff, which are fifty miles apart. It appeared lance-like for a few moments and then was seen to be bending like a floating ribbon, and also expanding in width, until it assumed the appearance shown at *B*.

A meteor having a remarkably persistent train ap-

peared over the south of England at 7.30 P. M., February 23nd, 1999. The train gradually increased in brilliancy, and twisted about, assuming grotesque shapes A part of it drifted to the northwest at a velocity of 80 miles an hour, and remained plainly visible until 9:30 or 10 o'clock, i. e., over two hours Another part drifted much faster; viz., at the rate of 300 miles an hour, according to the calculations of Mr Denning, the well-known English authority on meteors.

Prof. Trowbridge finds that the altitude above the earth's surface at which persistent meteor trains occur when seen at night is usually confined to definite limits between forty-five and sixty-five miles; though the path of the meteor may extend far above and below these limits. He terms this stratum of the atmosphere the *meteor train zone*. He assumes therefore, that in this zone there are conditions favorable to both the formation and the persistence of the luminosity of the trains, and he believes that the principal condition is the pressure of the atmosphere at that particular elevation.

He explains the train as a phenomenon of luminescence, similar to the afterglow following an electric discharge in a vacuum tube. When a body in very hot an immense number of negatively charged corpuscles or ions are given forth from it. Air containing free ions becomes a conductor of electricity, hence we have in a meteor rushing through the atmosphere a condition very like a long electrical discharge tube containing a gas at low pressure; the passage of the meteor-forming a column of highly ionized air thirty or forty miles in length.

Experiments with vacuum tubes containing air of about the same density that is supposed to occur at the altitudes in question, and from which the oxygen has been mostly extracted, give the same slowly-fading afterglow, following an electric discharge Thus, according to Prof. Trowbridge, it is not unlikely that the production of the light of a meteor train is connected directly with the highly ionized state of the air produced by the outpouring of electrons from the intensely heated meteor.

The rapid lateral expansion of the train is explained as due mainly to gas diffusion, and the rate of such diffusion depends upon the pressure and the temperature of the gas Accurate observations of the expansion of these trains should therefore aid in determining the pressure and temperature of the atmosphere at the altitude at which the train occurs Further the drift of the train furnishes a means of determining the direction and speed of the air currents at these great altitudes, which are far beyond the range of meteorological balloons

Whatever may be thought of Prof. Trowbridge's explanation of the physical nature of meteor trains, it is clear that their systematic observation should be considered a most important part of the general campaign of upper air research which is now engaging the earnest attention of meteorologists and astrophysicists

The Odor of the Rainbow

EVERYBODY has heard of the pot of gold buried at the end of the rainbow, but there is another old belief connected with this meteor that is not so familiar nowadays The attention of meteorologists was called to it, a few years ago, by Mr Richard Bentley, of the Royal Meteorological Society

It appears that over half a century ago a controversy took place in the English newspapers as to whether the rainbow emitted an odor A belief in such an emanation existed in antiquity, and has been echoed by several modern poets Thus it is mentioned in Pliny, Aristotle, and a Greek writer referred to by Coleridge, in his "Table Talk", in the "Peripatetic Philosophy" of Georgius de Rhodes; in Bacon's "Sylva"; in Browne's "Britanufa's Pastorals," and more lately in a poem by Robert Snow.

The origin of this curious belief is explained by Mr Bentley as follows Everyone is familiar with the increase of scent given off by plants and shrubs on a warm evening after the air has been newly washed by rain. This would naturally often coincide with the appearance of a rainbow

A New Miniature Projection Apparatus Suitable for Legal Photography

THE photographic work of experts in criminology is carried out usually with the aid of artificial light, at least when microscope objectives are used In these cases the surface to be illuminated is usually only an inch or two wide, but the illumination must be intense and very uniform The small projectors which are used by physicians for the examination of the eye and throat are ill suited for this purpose A writer in *Die Umschau* describes Geiger's new miniature projection apparatus, which may be used for photography as well as for other purposes As the accompanying illustration (Fig 1) shows, the apparatus consists essentially of a stand carrying a resistance box and the lamp with its housing and projecting lenses. The lamp is a self-regulating, or fixed point, electric arc, which consumes about 3 amperes of current, can be used on ordinary incandescent circuits and yields an exceedingly uniform light of about 300 candle power The two projecting lenses are mounted in a draw tube, by extending which more or less the diameter of the illuminated circle may be varied from an inch or two to twelve inches Even with the largest circle the illumination is sufficient for photographic purposes The size of the circle can also be limited by the use of diaphragms. The lamp can be moved vertically and horizontally on the stand, and the upper part of the stand carrying the lamp, can be inclined at any angle by means of the joint and screw shown just below the resistance box. The projector is also provided with a mirror which can be turned and inclined in any direction. By means of these various adjustments the dimensions and direction of the cone of light can be adapted to any purpose This flexibility of the apparatus will be found especially valuable when the working space is limited

This apparatus will be found very useful for scientific photography in many fields Here we will mention only its employment in photographing the so-called latent finger marks which are often used for the identification of criminals. Although these marks are called latent, they are not strictly invisible, but only difficultly visible, that is to say, a special kind of illumination is required to make them sufficiently conspicuous to be photographed Various devices for producing such illumination are described in special treatises Among these methods that of Stockis is the most successful, but it requires a special projec-

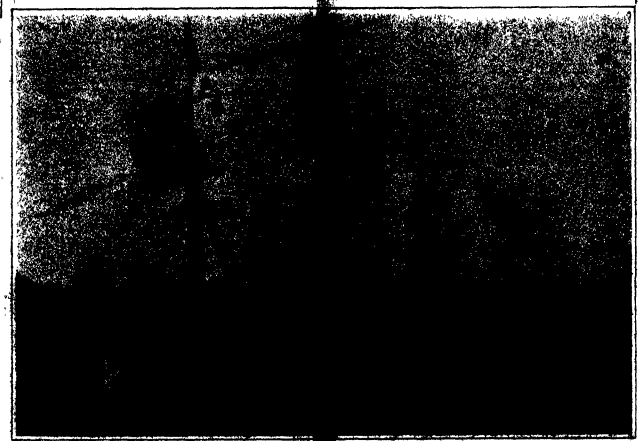
finger impression are intensely illuminated and appear on the positive photograph as white lines on a black ground Figure 3 shows a negative impression obtained directly in the camera on bromide paper by this method This negative shows the papillary lines black on white ground, and is hence directly comparable with the impression of the blackened finger on paper The great simplicity of this method should lead speedily to its general employment in criminal practice

This view was taken from off the port side. To the left is a boat crane. Abaft is a portion of a deck, which was blown up and back, exposing its under side. Abaft of this is the mainmast. The projecting material to the right is standing on the submerged poop decks. Beyond this is the "Kentucky" or "Kearsage."

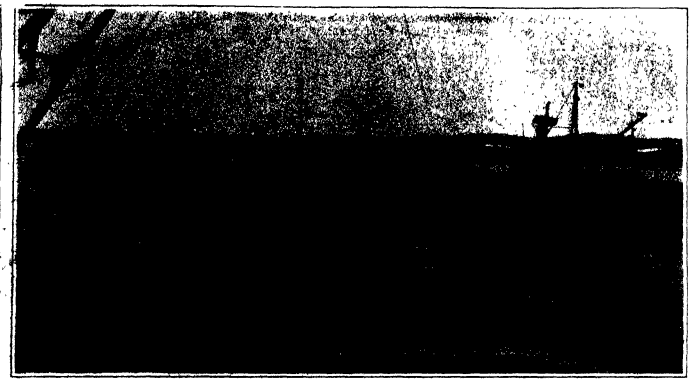
THE "MAINE" AS SHE APPEARED AFTER THE DISASTER



The Mystery of the "Maine"

Searching for the Cause of the Explosion

By Ludwig [illegible]ler, C. E.



(Special Cor[illegible] at Havana)

["I was just closing a letter to my family when [illegible] the crash of the explosion. It was a bursting, rending and crashing sound or roar of immense [illegible] largely metallic in its character. It was succeeded by a metallic sound—probably of falling [illegible] a trembling and lurching motion of the vessel, then an impression of explosion, attended [illegible]es of the electric lights and intense darkness within the cabin. I knew immediately that the [illegible] had been blown up and that she was sinking. I hurried to the starboard cabin ports, [illegible] be necessary for me to make my exit in that way. Upon looking out I decided that I could [illegible] passage leading to the superstructure. I therefore took the latter route, feeling my way along the [illegible] bulkheads. The superstructure was filled with smoke, and it was dark. [illegible] the outer entrance I met Private Anthony, the orderly at the cabin door at the time. He ran [illegible], and, as I remember, apologized in some fashion, and reported to me that the ship had been blown [illegible] and was sinking."—So testified Capt. Sigsbee before the Naval Court of Inquiry into the Maine disaster. It is fitting that his dramatic story should be rewritten above these photographs showing the ship as, thirteen years later, she emerges from the waters of Havana Harbor.—Ed.]

The "Maine" in these days would be accounted an [illegible] ship. She was 318 feet long, of 6,682 tons displacement and 17.4 knots speed; carrying four 10-inch and six 8-[illegible] guns. She carried twelve inches of armor amidships.

THE "MAINE" AS SHE APPEARED [illegible] SHORTLY BEFORE HER DESTRUCTION

The caisson consists of twenty more or less independent steel cylinders about 50 feet in diameter, constructed around the wreck in elliptical form. As soon as all the cylinders were in place they were filled with earth dredged from the harbor.

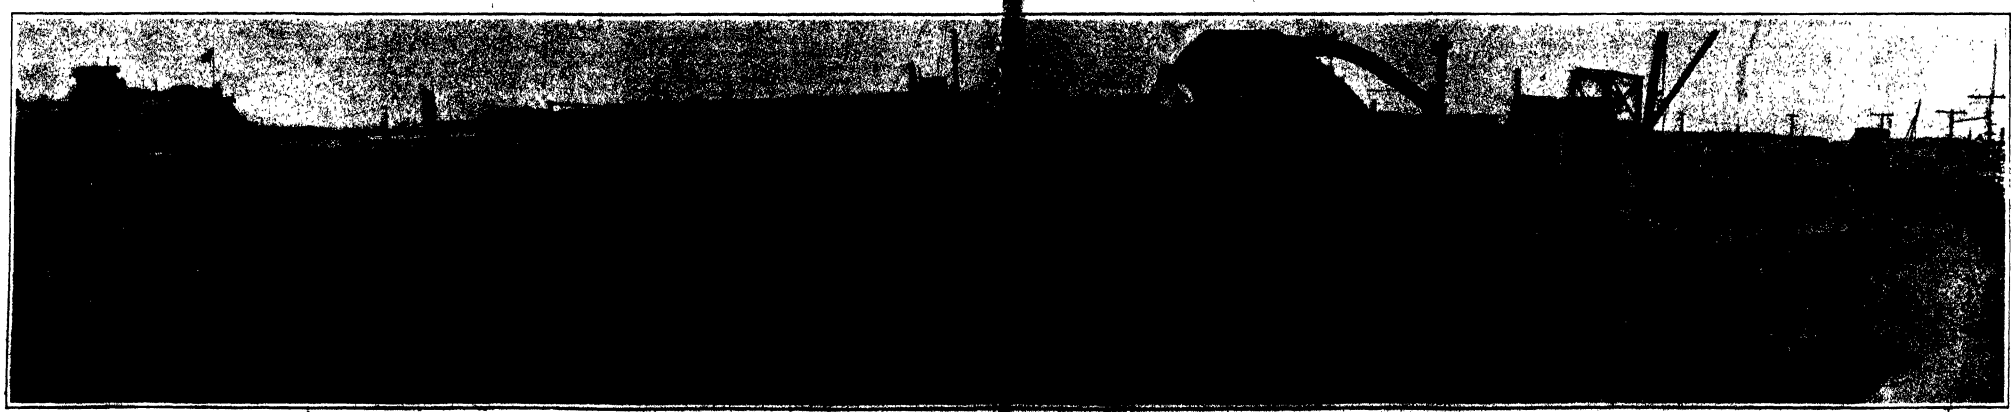
A SECTION OF THE CAISSON

THE work of raising the wreck of the "Maine" from its thirteen years bed in Havana harbor has now progressed to such an extent that an intelligent idea may be had of the undertaking, the force of the explosion and permit of a consideration of the caisson or cofferdam being used in this work.

The wreck originally lay in about 35 feet of water, but the actions of the tides have raised the mud level over 5 feet, while the remains of the hull have settled into the mud about 35 feet. As the bottom of the wreck is not less than 60 feet below sea level, the caisson must finally sustain a pressure of 30 feet of water and 30 to 35 feet of mud before the hull of the vessel will be exposed either for examination or removal. The original idea of the engineers in charge of the work was to pump out the water and mud to this level, to uncover the entire wreck and determine, if possible, the cause of the explosion. The recent developments of the works have made it necessary to modify these plans, because the caisson has not developed the estimated strength.

The design of this caisson is somewhat of an innovation and must be considered more or less as an experiment, this being the first practical test on any large undertaking. It has not proved an entire success, and whether the defects that have developed can be remedied and this system perfected for future use is a matter for the engineers and the owners of the patents to determine, but from the results obtained in Havana the system does not seem quite feasible.

The caisson consists of twenty steel cylinders about 50 feet in diameter, constructed around the wreck in an elliptical form. Each cylinder must be considered more or less as an independent unit, as there is a foot of space between each of the cylinders, which space has been closed in on the outside line by a 15 foot segment of a cylinder, and on the inside with a wooden pile. The cylinders are built of 150 straight, steel, interlocking staves, about 75 feet long. The staves were driven one at a time around circular forms with insufficient false work, and care was not used in the driving to keep them plumb, the result being that the top of the circle was completed sooner than the bottom, which spread in many cases as much as 24 inches, and in a few others even more. The last stave driven, which completed the cylinder had to stand the strain of closing in the open space and drawing the bottom circle into line with the top. The interlocking jaws of the staves in some cases could not stand the strain and have splintered and cracked.



As soon as all the cylinders were in place they were filled with earth dredged from the harbor. The filling of the cylinders became necessary to make the joints between the staves watertight and to prevent the steel shell from crushing under the water pressure. The strength of the caisson is derived from the earth confined within the cylinders. What this strength will be is an open question. Where the caisson would fail if tested to the breaking point is hard to say. There must be at least 10 or 15 feet of slime and soft mud in the cylinders at the level of harbor bottom. The caisson is, therefore, weakest at this point where the water pressure is greatest, so failure might be expected at about 30 or 35 feet below sea level, or at the bottom of the harbor, provided a cylinder did not become detached and forced out of place.

When the caisson was completed and filled, the water was removed by degrees until a 15 foot level was reached before any signs of stress developed. At this point a thorough examination was made which showed that the various cylinders were moving, those of the side faster than those on the end, that the caisson, owing to the space between the cylinders, was not a complete unit, but composed of twenty separate parts each one acting independently. Besides this an examination below water by the divers showed that the staves of the cylinders were strained as mentioned above, and that they required immediate reinforcing. The water level was at once raised about 5 feet and maintained at the 10-foot level, while the caisson was being strengthened.

Seventy-five thousand tons of stone and rock have been dumped within the caisson and banked against the cylinders. This stone, of course, has sunk into the mud and raised it from about 30 feet to 22 feet below the sea level, so the wreck to-day is buried in about 40 feet of mud. The stone fill has strengthened the caisson, but has not stopped the movement of the cylinders. Many of them are 3 to 4 feet out of plumb, inclining toward the center. The original movement of the cylinders, before the stone fill, under the pressure of the 10 foot water level, was 1½ inches in 24 hours, while now with the rock reinforcement and with the water removed to the mud level, or about 22 feet below the sea level, the movement has been reduced to about ½ inch in 24 hours.

The stone reinforcement encroaches upon and banks against the bow and stern of the wreck, while in the wider parts of the caisson the wreck is still entirely free. As the 40 feet of mud is being removed from the line of the wreck, the weight of the stone will force the mud from beneath the stone, thereby causing it to settle deeper and deeper into the caisson. This will require additional stone reinforcing, as the reinforcing must be maintained around the top of the cylinders, to prevent them from toppling over. As the volume of the reinforcement is increased the embankment will encroach more and more upon the wreck.

To correct this evil at the bow and stern it has been found necessary to place a single line of steel sheet piling as close to the wreck as practical, to retain the mud and stone against the cylinders, and prevent any further encroachment upon the wreck. This sheet piling will have to be braced to the wreck itself to withstand the pressure from the caisson, while the mud is being removed.

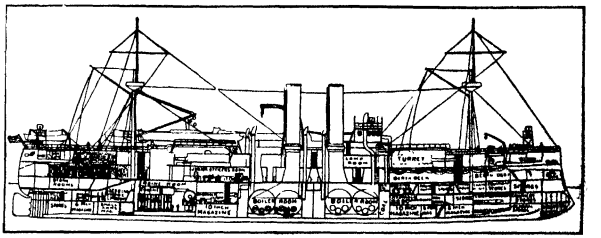
What is left of the bow, with portion of deck thrown up and back upon it with under side exposed.

This gap shows the region of the explosion. It represents the explosive energy of the 10-inch and [illegible] magazines; which blew out the sides, lifted the decks and folded them back upon the ship.



The central superstructure, with portion of deck folded back upon it. Note [illegible] armored side of ship with its square portholes.

The after turret with two 10-inch guns all intact.

Poop deck with portholes shutters still raised.

PANORAMIC VIEW SHOWING "MAINE" WRECK AND [illegible] COFFERDAM WALL WITH ROCK PILING AT ITS FOOT

A summary of the work, as it stands to-day, seems to show that the caisson is constructed of twenty separate units, which lack sufficient strength to withstand the pressure until filled, that the fill is of a nature not to withstand much pressure, that the cylinders were strained in placing, and that an additional row of sheet piling is required to keep the reinforcement free of the wreck. The caisson has proved not only inefficient, but very expensive. The first appropriation of half a million dollars was expended some time ago when the work was only half finished, and another half million will be required before the work is completed.

This longitudinal section of the "Maine" shows the location of the magazines.

While the caisson cannot be considered an engineering success it has permitted of the removal of the remains of our "hero dead." There are still many bodies unaccounted for and always will be, because the force of the explosion blew them free of the wreckage and into the harbor, but all the bodies confined within the wreck can and will be recovered. On August 12th the cruiser North Carolina arrived in New York harbor with the remains of Lieut. Merritt, one of the two officers who lost their lives. After all the remains have been recovered they will receive a fitting burial, with all the honors due brave and true men.

The cause of the explosion will never be learned if it was primarily of an external origin there will be no traces of it found to-day. The forward magazines have exploded and the hull is practically cut in two. The bridge and the conning tower with part of the decks and hull have been turned completely upside down and folded back upon the main deck amidship, while the bow is turned completely inside out and is a mass of unrecognizable junk. For a space of about 100 feet between the wreck of the bridge and the bow, soundings in the mud fail to show any trace of the hull. From midship to the stern the wreck is practically intact and can be raised without difficulty by building a bulkhead back of what was the bridge. The bow will have to be removed piece by piece by cutting the wreckage apart with acetyline torches. A plant for this work has been installed, with torches that cut through the steel wreckage like a knife through cheese. This work is already under way and part of the wreckage has been removed.

A wooden model of the "Maine" is in the engineer's office and piece by piece the model is being dismantled as the wreck itself is being cut apart. Several months must still pass before the wreck will be ready for its final burial in the deep waters of the sea, and the last visible sign of the wreck of the "Maine" will have been destroyed forever, excepting only such parts as the government may preserve for fitting memorial monuments to those who, without a moment's warning were sent into eternity by the explosion of the ship's magazine, the cause of which will forever remain unknown.

The Technical Museum of Vienna

THE Technical Museum in Vienna publishes a circular stating that in commemoration of the sixtieth anniversary of Emperor Francis Joseph's reign, Austrian manufacturers with the assistance of the State and the City of Vienna initiated this new museum. The foundation stone was laid on June 20th, 1909, and the building, which covers an area over 20,000 square yards, and which is situated opposite the palace of Schoenbrunn, is now nearing completion and will be a lasting monument of the monarch.

This Technical Museum is to demonstrate the development of industries and crafts in historical succession also to do justice to the technical achievements of the present day, and to promote progress in this line by periodical exhibitions. It is to be a public educational center, spreading the knowledge of the scientific foundations and the national economic aims of technical pursuits.

A considerable stock of objects has already been secured, as several large and valuable state collections, till now dispersed, are shortly to be brought together there. But many links in the chain of technical development are still missing. Therefore technical scientists, manufacturers and craftsmen of all countries are invited to co-operate in this great task and to assist the museum in procuring and selecting suitable objects. Everything pertaining to technical labor is acceptable, principally tools, machines, apparatus, models, materials, methods of working, finished articles as well as plans, designs, books, illustrations and manuscripts. The Austrian government has placed at the exhibition's disposal the halls of the Rotunde ("Prater") for the present storing and sifting of arriving donations. The names of donators will be perpetuated by inscription on the gifts and in a memorial book. Further particulars can be obtained from the office of the Technical Museum, Vienna, I Ebendorferstrasse 6.

Destruction of Banknotes

IT WILL come as a surprise to those whose chief difficulty in regard to banknotes is to be able to keep them to learn that there are yet others for whom the difficulty is how to get rid of them. Yet this is quite true in the case of those who have to destroy in bulk paper which has been used in representing money values. The difficulties thus encountered in destroying such paper are well illustrated by the experience of the German Imperial printers.

In this case the difficulties experienced are further increased by the necessity of coping with very large quantities of waste, for in addition to that arising from printing there is also that of stamp paper spoiled in the gumming as well as faulty water-marked paper.

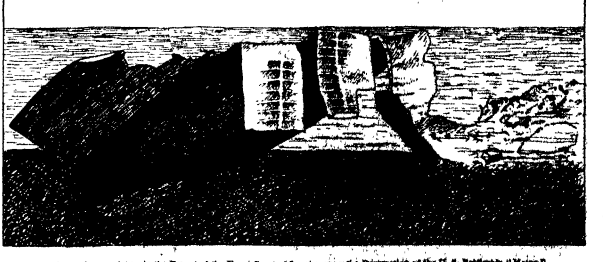
The methods previously available were three—burning, boiling and pulping. In the first process it has been found even where a special furnace has been used, it has not infrequently happened that while the outer parts of the packets were destroyed some of the contents were not even singed. In the case of stamps or gummed paper the matter was still worse, for the packets baked together into solid blocks, the interiors of which were quite intact.

In the second process the paper for destruction is placed in iron boilers; lye is added and the contents then subjected to the prolonged action of steam. As a destructive process for small quantities this is most effectual, as is also that of pulping, a process in which the paper is cut up by revolving knives in water. In both of these cases there is, however, another difficulty, that of disposing of the product. It cannot be easily sold, it will not pay to transport and on hand the sodden stodgy mass quickly "goes bad."

The German imperial printers therefore decided to try a new way—grinding it up dry. To this end they installed a 40 horse-power Schlagkreuz mill, which by a process of hurling, crushing and tearing reduces the paper to an almost powderlike form in which it passes through a sieve into a collecting chamber beneath the mill ready for packing. This, however, was accompanied by a very objectionable feature, especially when dealing with gummed paper in the grinding—such a dust was created that though the workmen engaged wore protectors, it yet persistently filled and blocked their eyes and nostrils.

As the work of packing was on this account not only unhealthy, unwillingly performed and also uneconomical, efforts were made to find some mechanical means of doing it. Simple as this had seemed at the outset, later it appeared a problem almost insurmountable. Difficulty after difficulty arose. Among such may be mentioned that a spiral feeder having been devised it was found that the paper would some times form into balls as solid as blocks of wood, which defied the efforts of a 20 horse-power motor to move them. Nevertheless this difficulty was ultimately overcome.

The imperial printers, therefore, are now to be congratulated upon possessing a machine perfect in its kind. It takes the paper, grinds it up to any size desired and bags it. Finally though the paper in this form fetches but little on account of its consequent shortness of fiber, the mill is yet not only paying off the initial outlay, but is also saving some $250 a year in workmen's wages.



A National Bureau of Markets

ON August 14th a bill was introduced in the House of Representatives providing for the establishment of a new branch of the Department of Agriculture, to be known as the "Bureau of Markets." The duty of the proposed bureau, as defined by the bill, is to be "to make diligent investigation of the methods of marketing farm products, and especially with regard to finding out and recommending the fairest and most direct method by which farm products may reach the consumer from the producer, by accumulating and distributing information on the subject in question and on the subject of the best methods and best markets for selling."

While the language of the bill is somewhat confused, it is evident that a step of much economic significance is contemplated. It is the order of the day to throw light upon the mechanism of trade; and it is in harmony with the progressive ideas now being conspicuously fostered by the International Institute of Agriculture to bring scientific methods to bear upon the marketing of farm products. We believe that a work of far-reaching beneficence awaits the Bureau of Markets, and hope that Congress will see fit to give it being.

Tramways in Monte Video

ACCORDING to a Consular Report, the United Electric Tramway Company of Monte Video, which was formed and registered as a British company in 1904, owns and works 131 kilometers—82 miles—of lines in Monte Video, with 195 motor passenger cars and 68 trailers.

The Inventor's Department

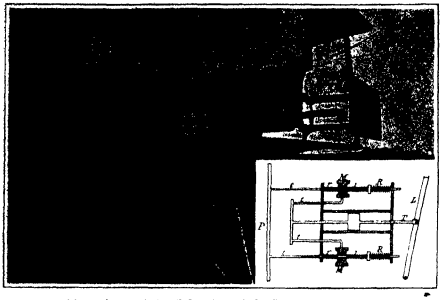
Simple Patent Law; Patent Office News; Inventions New and Interesting

The Doutre Automatic Stabilizer

THE all too numerous accidents to aviators place the question of automatic stabilizers in the very forefront of interesting inventions. The ideal equilibrator would be one which would act in two directions, both laterally and longitudinally. Many attempts along this line have been made but hitherto have proved unsatisfactory. A very interesting new departure is a stabilizer invented by M. Doutre. This stabilizer has been installed upon a Farman biplane actuated by a 60-H.P. Renault motor. The well-known aviator, Didier, flew with the machine first alone and then with a passenger, and performed several flights which demonstrated the efficacy of the apparatus. In one trial the machine flew very successfully in a 36 mile wind.

The Doutre stabilizer acts upon the longitudinal equilibrium only. Under three conditions this equilibrium is affected, viz., by the slowing down of the motor, gusts of wind from the front, and gusts of wind from behind, which cause the machine either to rear or plunge to the ground.

To overcome the pitching, the aviator must turn the elevator in the direction of the pitching. But the pilot has not always the presence of mind nor even the time to carry out all these movements. The automatic stabilizer, it is claimed, claims to fulfill these functions spontaneously.



The stabilizer comprises two essential parts: First, a plane surface, moving a vertical plate in a sliding frame, and presenting its face to the wind, which causes it to recede more or less according to the intensity of the wind. This plate practically constitutes an anemometer which responds to the pressure of the relative wind. Secondly, there is a member which follows the displacements of the plates and transmits them through a system of joints to the horizontal rudder or elevator.

The movable resisting surface is a rectangular aluminium plate supported upon rods which slide in the frame of the machine, being maintained in a fixed position through the tension of a spring when the wind is normal. If the relative wind increases, the aluminium plate moves back in proportion to the resistance and returns to its former position as soon as the excess pressure disappears. Similarly, in case there is too little pressure, the aluminium plate moves forward under the action of the spring.

The sliding rods of the aluminium plate are connected with a central rod T which enters the cylinder of the compressed air auxiliary motor, controlling the piston of the same; it passes out of the other end of the cylinder, and actuates a lever L which controls the horizontal rudder of the aeroplane. It will, therefore, be understood that when the springs and lever joints are suitably adjusted, the movements of the aluminium plate under the action of the relative wind cause the admission of compressed air into the auxiliary motor, in proportion to the displacements of the piston rod, in one direction or the other; in this way, through the intermediary of the rear rod, the horizontal rudder or elevator is automatically controlled.

This apparatus, while effective by itself, is supplemented by another member which takes account of another factor bearing upon the equilibrium, namely, the weight and inertia of the masses. Thus, for instance, if the aeroplane should start to plunge forward and downward, the increasing relative wind would force the aluminium plate to its rearmost limiting position, and the elevator would be set in its normal position; the aeroplane would then continue in its course, heading for the ground. It would require a special act on the part of the pilot to restore the machine to its normal position. This, then, would not be completely automatic working. To overcome this defect the inventor provides a pair of small weights M mounted upon the sliding rods of the aluminium plate P and each maintained by two springs in such position that in normal flying the small weights follow the rods in all their movements. But as soon as the speed of the aeroplane changes, which will happen every time its course is deflected from the horizontal, these weights are either thrown forward or backward on account of the change of speed and their inertia. They thus overcome the tension of one or the other of the springs between which they are placed, and are displaced with reference to the rod upon which they rest. These weights are connected with the piston rod of the auxiliary motor which thus receives from them the atmospheric impulses impinging upon the aluminium plate.

In consequence of this not only is the auxiliary motor (through the intervention of the aluminium plate and the motion of the small masses together) placed under the influence of the relative wind but also under the influence of the longitudinal pitching of the aeroplane, through the motion of the small masses alone. Accordingly, the elevator obeys automatically one or the other of these external influences, and the longitudinal equilibrium is restored.

Near view and detail drawing of the Doutre stabilizer.

General view showing arrangement of the Doutre stabilizer on the aeroplane.

Redrawn from the *Illustrated London News* of June, 1850

An early transatlantic boat cruise.

An Early Transatlantic Boat Cruise

THE accompanying illustration, reproduced from an old volume of the *Illustrated London News* (June, 1850), presents a picture of quaint historic interest. The little boat, the "City of Ragusa," measured 20 feet in length and 6 feet in breadth of beam. Her registered burden was 1¾ tons. There was a small cabin, 3 feet wide and 4 feet 6 inches high. The boat, in its original form, belonged to the ship, "Breeze," which foundered in a storm in the Irish Channel and fourteen of the crew were saved by the boat. As shown in our illustration she is rigged as a yawl, arranged to set square sails on both masts, spreading altogether 70 yards of canvas in 8 or 9 sails. But she is also furnished with a two-bladed screw propeller which, so we read—can be worked either by hand or by a windmill as shown in the illustration. We leave it to the reader to make his own comments on this mechanism.

Two valiant men, Capt. Buckley and an Austrian Italian, named Pietro Di Costa, planned to cross the Atlantic in this tiny craft. They left Cork Harbor on the evening of Thursday, and were last sighted by a pilot cutter forty miles west of Cape Clear. Of their subsequent fate our source tells us nothing.

Electric Lamps for Miners

THE following copy of the conditions of entry for a competition to be conducted by the British government for advertising a safe and efficient type of electric lamp for miners has been furnished by the United States Bureau of Mines, also by the British Ambassador in Washington.

His Britannic Majesty's government announces that, in order to encourage the production of safe and efficient types of electric lamps for miners, a colliery proprietor has placed at their disposal the sum of £1,000 ($4,866.65) to be offered as a prize for the best lamp or lamps fulfilling the requirements specified below.

Mr. Charles Rhodes (a former president of the Institute of Mining Engineers) and Mr. Charles H. Merz (a member of the departmental committee on the use of electricity in mines) have consented to act as judges. The conditions of the competition are as follows:

1. The competition will be open to persons of any nationality.

2. It will be in the discretion of the judges to award the whole of the prize for the lamp which they consider to be the

best, or to divide the prize, or to make no award if no lamp appears to them to be of sufficient merit

4 Lamps must be addressed care of C. Rhodes, Esq., at the Home Office testing station, Rotherham, England, and must reach the testing station not later than December 31st, 1911. A spare globe should accompany each lamp

The requirements which should be fulfilled by any lamps submitted for competition are as follows

1 The lamp should be of sound mechanical construction, so as to withstand rough usage

2 The lamp should be of simple construction and easy to maintain in good order and repair

3 The lamp should be so constructed as to render impossible the ignition of inflammable gas either within or without the lamp

4 The lamp battery should be so constructed that any liquid which it may contain cannot be spilled when the lamp is in use, and means should be provided for dealing with any gas which may be generated by the battery

5 The materials used and the construction should be such that metals and other parts will not be liable to deterioration by corrosion as a result of the action of the "electrolyte," etc., used in the battery

6 The lamp should be effectively locked so that it cannot be opened without detection

7 The lamp should be capable of giving an amount of light not less than 2 candlepower continuously for a period of not less than 10 hours

8 The light should be well distributed outside the lamp. A movable reflector to concentrate or to shield the light may be provided

In addition to the above requirements, regard will be paid to (a) the first cost of the lamp, (b) the cost of maintenance, (c) convenience in handling, and (d) the weight of the lamp when charged and ready for use.

Trade-mark Rules Amended

ACTING Secretary of the Interior Samuel Adams recently approved the recommendation of the Commissioner of Patents that certain amendments to the Trade-mark Rules be adopted to take effect November 1st, 1911

The amendments are as follows

To be inserted immediately following Rule 45:

45a If an applicant fail to prosecute his application within one year prior to November 1st, 1911, or for one year after the date when the last official notice of any action by the office was mailed to him, the application will be held to be abandoned as set forth in Rule 57a.

45b Whenever action upon an application is suspended upon request of an applicant and whenever an applicant has been called upon to put his application in condition for interference the period of one year running against such application shall be considered as beginning at the date of the last official action preceding such suspension.

45c Acknowledgment of the filing of an application is an official action. Suspensions will only be granted for good and sufficient cause and for a reasonable time specified

45d Only one suspension must be approved by the Examiner of Trade-marks. Any further suspension must be approved by the Commissioner.

The first paragraph of Rule 56 is cancelled. The paragraph is as follows

56 From an adverse decision of the examiner in charge of trade-marks upon an applicant's right to register a trade-mark, or to renew the registration of a trade-mark, or from a decision of the examiner in charge of interferences, an appeal may be taken to the Commissioner in person upon payment of the fee required by law.

For the above there is substituted the following:

56 Every applicant whose mark has been twice refused registration by the Examiner of Trade-marks for the same reasons upon grounds involving the merits of the application may appeal to the Commissioner in person upon payment of the fee required by law. Such refusals may be considered by the Examiner of Trade-marks as final.

There must have been two refusals to register the mark as originally filed, or, if amended in matter of substance, the amended mark, and, except in cases of division, all preliminary and intermediate questions relating to matters not affecting the merits of the application must have been settled before the case can be appealed to the Commissioner.

The remaining paragraph of Rule 56 stands unchanged.

Following Rule 57, which relates to the taking of appeals in trade-mark cases to the Court of Appeals of the District of Columbia, there is inserted the following:

57a An abandoned trade mark application is one which has not been prosecuted within one year prior to November 1st 1911, or completed and prepared for examination within one year after the filing of the petition, or which the applicant has failed to prosecute within one year after any action therein of which notice has been duly given, or which the applicant has expressly abandoned by filing in the office a written declaration of abandonment, signed by himself and assignee, if any, identifying his application by serial number and date of filing

57b Prosecution of an application to save it from abandonment must include such proper action as the condition of the case may require The admission of an amendment not responsive to the last official action, or refusal to admit the same, and any proceedings relative thereto, shall not operate to save the application from abandonment

57c Before an application abandoned by failure to complete or prosecute can be revived as a pending application it must be shown to the satisfaction of the Commissioner that the delay in the prosecution of the same was unavoidable

57d When a new application is filed in place of an abandoned or rejected application a new petition, statement declaration, drawing and fee will be required

The foregoing amendments to the rules of the Patent Office relating to the registration of trade-marks, for the most part, are a paraphrase of similar rules that have long been adopted and used in connection with the prosecution of applications for patents This 47a corresponds with Rule 77 of the Rules of Practice, 56 corresponds with Rules 133-134, 57a corresponds with Rule 171, 57b with Rule 172, 57c with Rule 172, and 57d with Rule 173, etc.

At the present time the practice in the Division of Trade-marks is and has been not to consider an application abandoned by reason of the failure of an applicant to prosecute it within a specified time There is every reason why this practice should not continue Under the present practice, the first application filed under the Act of February 20th, 1905, which was acted upon soon after, must be taken up for action whenever the applicant desires, even if no action has been taken by applicant in the intervening time As the result of this procedure and the accumulation of a large number of cases, the Trade-mark Division is seriously handicapped in the prosecution of its necessary business It is estimated that there are now on file about sixteen thousand cases not "awaiting action" in the Office, and that three-fourths of these cases filed prior to January 1st, 1909, have not been acted upon within one year

Under the rules as amended to take effect November 1st, 1911, it is believed that the present difficulties involved in making an issue search would be materially lessened This search is made once a week by each of the seven assistant examiners and necessitates examining every one of the sixteen thousand drawings This has become a severe burden and was rapidly becoming more so It is estimated that at the end of ten years there will probably be twenty thousand more drawings which, added to those that are already filed, would make thirty-six thousand drawings. To search these once a week is an appalling task When it is also considered that the search of the examiners is increasing in length each year, due to the increase in the number of registrations granted, it is easy to see that the system in vogue could not indefinitely continue It was desired, therefore, to confine, so far as possible, the energies of the examiners to the search proper rather than expending them uselessly in searching each week a large number of practically dead applications. This saving in time and labor on the part of the examiners will greatly facilitate better and more expeditious examinations.

The rules as amended seek to accomplish only, in connection with trade-mark applications what is now accomplished in connection with applications for patents by similar rules. The language of the rules follow somewhat closely the corresponding rules, so far as the language employed in connection with applications for patents is deemed applicable to applications for the registration of trade-marks. Moreover these rules are regarded as being in every way consistent with the statutes.

Notes for Inventors

Losing One's Way in the Air.—An army aviator, Capt Paul Beck, flying from College Park, Md., recently lost his way for an hour or so in the clouds and landed finally over in Montgomery County, miles out of his course. It appears that the ordinary mariner's compass is not satisfactory for use in the air, since the aviator cannot determine, after he loses sight of the earth, the extent to which he may have drifted laterally from his course The incident has stimulated renewed interest in the subject and Capt. Chambers, who has charge of naval aeronautics, is continuing his efforts to devise some means whereby aeronauts may be able to determine the course with reasonable accuracy.

A Medal for a Printing Office Employee.—On behalf of the Public Printer, Vice-President Sherman has presented the assistant foreman of the foundry section of the Government printing office at Washington, D. C., with a gold medal for an invention, hygiene in its nature, and operating to reduce the danger to health, resulting from graphite dust in electrotyping and printing.

A Domestic Cream Separator.—A domestic cream separator embodied in a milk bottle of the form commonly used by dairymen in delivering milk to customers is shown in a patent, No. 999,747, to Ada B Brown of Seattle, Wash It has an L-shaped tube journaled in an opening in its side at about the base of the neck and having an upturned wing in the bottle which, by turning the horizontal journaled wing, can be set to different heights to take cream from different levels and discharge it through the horizontal wing to the outside of the bottle.

A Fireproof Coil for Electrical Apparatus.—Seeking to provide a fireproof coil for electrical apparatus, Charles E. Skinner of Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company, has patented No. 999,893, a coil which has a plurality of turns of conducting material with a strip or layer of metal foil interposed between the adjacent turns, the foil being first treated to provide an insulating film on its surface.

A Moving Spiral Staircase.—The Otis Elevator Company has obtained a patent, No. 999,885, for an elevator which has a conveyer transporting between different levels in which the direction of movement is clockwise and contra-clockwise. The elevator is in the form of a moving stairway, having ascending and descending series of steps which travel in spiral paths in opposite directions about a common center of curvature The inventor is Charles Leeberge of New York city.

Printing by Sound.—A method of printing by sound is the subject of a patent, No 999,975, to Arthur C. Ferguson of Brooklyn, assignor of eleven-sixteenths to Lyman C. Smith of Syracuse, N. Y. By the method, the sound waves are recorded by utilizing a succession of said waves to initiate the operation of mechanism actuated by a separate source of energy for printing a legible character corresponding to certain tone characteristics of said waves. In other words, the character printing mechanism is actuated by a separate source of energy and the waves are utilized to control such source of energy.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and confidentially to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This contains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

BUSINESS OPPORTUNITIES

WHATEVER YOU MAY BE MANUFACTURING or thinking of manufacturing that may be advantageously manufactured in Wilmington, Delaware, If in on the Delaware River and on the main lines of the Pennsylvania and B & O Railroad. It is surrounded by beautiful country and is supplied by excellent markets. Manufacturer and operatives can live pleasantly and economically housed. It has already large manufacturing interests, such as ship building, car building woolen mills, textile works, tobacco works and powder works If you are in any way interested write for further particulars to the Development Department, Wilmington & Philadelphia Traction Company, 9th Market street, Wilmington, Del.

WHATEVER YOU MAY BE MANUFACTURING or thinking of manufacturing that may be advantageously manufactured in Chester, Pa It is on the Delaware River and on the main lines of the Pennsylvania and B & O Railroad. It is surrounded by beautiful country and is supplied by excellent markets. Manufacturer and operatives can be pleasantly and economically housed. It has already large silk works, woolen mills, textile works, engine works. The Baldwin Electric Works are now enlarging their plant. A specific established here. If you are in any way interested write for further particulars to the Development Department, Southern Pennsylvania Traction Company, 10th & Filbert st, Philadelphia, Pa.

MAIL DEALERS. Write for our $5 biz propositions. All new no competition Make $6 per cent profit on every dollar you invest. A $1 outfit free. Complete outfit, $30. Mail Dealers Wholesale House, 419 Franklin Building, Chicago.

PATENTS FOR SALE

ARTIFICIAL RAIN.—New system of irrigation combined with electrified wires. Rain and control fertilizer. Patented. Capital wanted to exploit same or will work on royalty basis. Patent for sale or for operating scale from fruit trees E. Olsson, 32 W 9th St., N.Y. City.

FOR SALE Gasoline Portable No. 2 Animal Dump A time and labor saver in dipping animals. Destined to fill a long felt want. For sale. For particulars, address Box 1, Plummer, Ashburn, Ill.

REAL ESTATE.

CALIFORNIA LAND, planted and separated by carpets, in a splendid irrigation district. Back lots (part of all crops. Write Geraldson Fruit Co., Newcastle, California (Packers Gladson & Fruit Co.)

ON THE HIGHEST HILLS and LARGEST LAKES, buy your cottage where you can get it. Cottage Land for Rent, on a new railroad, at a new town site. For full particulars, address C. W. Brown, Prospect, Fla.

WANTED.

LOCAL REPRESENTATIVE WANTED.—Established manufacturing concern, solid basis for district (heart of vortex motion). Master does not "build" together, attract." repel," or apply any of these forces into his contract. No "potential" energy. Only one ultimate element. Reverse motion (reaction) of certain kinds of all energy, and phenomenal; no, free energy measure. "An Amazing Discovery" perpetual motion (practical) all based upon system of levels. Orbital vortex motion of gathered cubes earth. Only a "few" sold. Dept. Pamphlet, ten cents, (coin). C. C. Clarke, Tuscola, Ill.

FREE—INVESTING FOR PROFIT" Magazine. Send set your name and I will mail you this magazine absolutely free. Solid facts for you to investigate—you (the) magazine it is worth $10 a copy to any one who intends to save $5 or more each month. Tells you how $1,000 grew to $10,000 in seven years. Tells you how $5,000 grew to $50,000 in seven years. Tells you how $10,000 grew to $100,000 in seven years. Tells you how to turn your money. This magazine costs you nothing if you write for it. Address Publisher Pamphlet, 68, 30 E. Jackson Blvd., Chicago.

$100 TO $10,000 MONEY. Securing a Patent. Free Booklet. Prompt, careful service. Highest references. Special attention given to applications rejected on the spot in ten minutes in the open street. Send rough sketch or model for free search. Experienced photographer to make first-class pictures. Let's a good proof of 30 for your model. Write for free booklet and instructions. Dept. 68 Search Bureau, Washington, D. C.

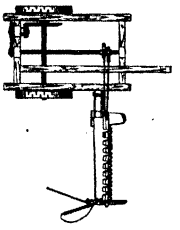
TYPEWRITERS, All Makes and Descriptions, Cheap. A mathematical apparatus, adaptable for schools, homes and libraries. Also a set of mathematical charts. Complete. Time and Distance problems. For descriptive circular and booklet, write C. A. Hart, Seattle, Wash.

MOTORCYCLES CHEAP.—Send to-day for free catalog of new and used motorcycles. A few reconstructed motorcycles and attachable motor outfits for converting bicycles into motorcycles. Motorcycle Manufacturing Company, Dept. 9, Pittsburgh, Pa.

THE MODERN SCIENTIFIC METHODS—Detective Training Course. Secret Service Training Course. Write for free booklet. Write to-day. Address Bureau of Criminal Investigation, Dept. 68, Detroit, Mich.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.



Electrical Devices.

HIGH TENSION STRAIN INSULATOR.—L. Steinberger, New York, N. Y. This insulator is for general use where currents of high potential are employed, it being especially well adapted for use in wireless telegraphy and telephony. Mr Steinberger's special purpose is to provide a number of novel constructional features in order to improve the general efficiency of the insulator, and to enable him to make it of an insulating material formed under pressure or molded, or of porcelain, glass or such like material, and to employ tension members of a rigid or of a flexible character, as may be desired.

ELECTROMAGNETIC VIBRATOR FOR LOCAL APPLICATION TO THE PERSON.—A. Rosenberg, London, England. This vibrator is for use for the production and local application to the person, of continuous, rapid, and intense mechanical vibrations of oscillations suited to the treatment of various maladies which are curable of being temporarily or permanently ameliorated by the application thereto of the mechanical vibratory massage and to the combination with the instrument of means whereby a pulsatory electric current may be passed through the body from the point of application thereto of the vibratory treatment and simultaneously with the latter

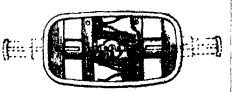
Of Interest to Farmers.

CUTTING MACHINE.—Clarence Shaw, Johnstonville P. O., Lassen Co., Cal. This invention relates more particularly to cutters and rearthers for cutting grain and the like, and the object is to provide a device for cutting down grain and the like when it is desired to harvest the same For the purpose mentioned, use is made of a vehicle chassis provided with a cutter frame having a plurality of cutter bars thereon and connected with

CUTTING MACHINE

eccentric means, secured to suitable driving means in engagement with the wheels of the vehicle, to operate the cutter bars, and a weather secured to one end of the frame for dividing the cut and uncut grain and for substantially preventing the latter passing through the cutter bars after the same has been cut down The engraving shows a plan view of the machine

Of General Interest.



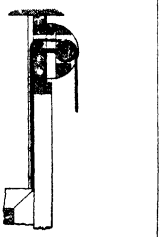
JOINT FOR ARBORS.—H. S. Davis and J. C. Hayden, P. O. Box 342, Port Hope, Ontario, Canada In this case the purpose is to provide joints for arbor sections used in castings which will permit the sections to be readily separated by striking one of the ends of the arbor and breaking the wedge member holding the sections together Another object is to so construct the sections that they will be held together by a wedge member of combustible or fusible material, the rigidity of which is lost by the heat and by contact with the metal, thereby permitting the sections to fall apart as the casting is removed from the same.

BASE FOR CARDBOARD FIGURES.—H. G. Fearns, Philadelphia, Pa This invention refers particularly to miniature cardboard figures in the shape of dolls and the like, and the object is to provide a form of base for holding the cardboard figure Wood and metal are ordinarily employed for the purpose, aside from the expense, they leave much to be desired in applying the base to the figure and the secure holding of it in place, while the present base permits of employing a figure made from much lighter cardboard than is really practical with a wooden or metallic base.

Hardware and Tools.

COMBINED LOCK AND RETAINING DEVICE.—M. Jasenska, New York, N. Y. In this instance use is made of a bolt slidably mounted in the inner end of a receptacle to engage the casing thereof, actuating means mounted on the outer end of the receptacle, and a flexible connection disposed between the actuating means and the bolt so that the bolt will automatically engage the casing when the actuating means are operated and the bolt being normally positioned so that the receptacle cannot be entirely withdrawn from the casing.

LOCK.—Raffaele Fiola, 2 East 120th Street, New York, N. Y. A rear elevation of the lock is reproduced in the illustration which shows the bolts projected in dotted outline. The lock serves the purposes of the ordinary padlock, which, when in position prevents the staples or eye-bolts from being cut or filed, and which renders difficult other unauthorized



LOCK

methods of opening the lock The bolt proper is operated by key-controllable mechanism of the pin tumbler type, which permits of a large number of variations in the key-controllable mechanism, and which may bring the casing of difficult shapes adapted for use with different kinds of doors or other closures.

Household Utilities.

SASH CORD GUIDE.—James P. O'Reilly, Hayden, Ariz. By the old construction and method of attachment, it is necessary to bore two holes one-eighth of an inch deep in the window jamb and then three more completely through the frame and finally to chisel out the triple bore to form a mortise adapted to receive the pulley frame In carrying out

SASH CORD GUIDE

the present invention it is required to bore only one hole and through the jamb, and then to insert therein a holder cylinder having interiorly, a small sash-cord pulley, and on the projecting end of the cylinder the frame containing the usual sash cord pulley is hung detachably the engagement being effected by a sliding joint The engraving is a vertical section of window frame or joint, with the attachment applied thereto

Machines and Mechanical Devices.

AUTOMATIC PHOTOGRAPHIC PRINTING MACHINE.—Giomo W. Ferguson, 314 Boonville Street, Springfield Mo The present device is an improvement over that disclosed in the prior patent No. 957,668 granted to Mr Ferguson The aim of the present invention is to provide devices for timing the exposure Those include novel means for switching on and off the circuits, and for controlling the same A further object is to provide a remov-

AUTOMATIC PHOTOGRAPHIC PRINTING MACHINE.

able lamp holder which may be quickly removed from the device so as to replace the lamps in case they become broken, and as quickly replaced, the replacement of the holder serving to again bring the lamps into circuit The illustration herewith represents the main box, the end being removed for the sake of clearness.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

It's Hard Work Like This That Makes Perfect Every

Waterman's Ideal Fountain Pen

The very life of a gold pen lies in its TEMPER, in the small space between the point and the little heart-shaped opening.

There it is that the necessity for experience comes in, coupled with keen judgment, in the skilful tempering of this most vital part of the Gold Pens in Waterman's Ideals.

The difference between a Waterman's Ideal and the other kinds of pens, is just the difference between ordinary, unthinking, machine work and the rare combination of active brain, experience, judgment and skilful hand.

Every pen that bears the name "Waterman's Ideal" has passed through the hands of a master workman. Every pen, therefore, with this famous name is the product of scientific knowledge and skilled labor.

There is a volume of reasons for pen superiority.

Alcohol

Its Manufacture
Its Denaturization
Its Industrial Use

Valuable articles in the *Scientific American Supplement*

Send for our 1910 Supplement catalog free to any address

1550 The Cost of Manufacturing Denaturized Alcohol in Germany and German Mode of Denaturization are discussed by Consul-General Frank H. Mason

1596 The Use, Cost and Efficiency of Alcohol as a Fuel for Gas Engines are ably explained by H. Diedrichs many clear diagrams accompany the text The article considers the fuel value and physical properties of alcohol and gives details of the alcohol engine, wherever they may be different from those of a gasoline or crude oil motor

1581—The Production of Industrial Alcohol and its Use in Explosive Motors are treated at length valuable statistics being given of the cost of manufacturing alcohol from farm products and using it in engines

1599—French Methods of Denaturization A good article

1603, 1604 and 1605 The most complete treatise on the Modern Manufacture of Alcohol, explaining thoroughly the chemical principles which underlie the process without too many wearisome technical phrases, and describing and illustrating all the apparatus required in an alcohol plant. The article is by L. Baudry de Saumer, the well-known French authority

1607, 1608 and 1609—A Digest of the Rules and Regulations under which the U. S. Internal Revenue will permit the manufacture and denaturization of tax free alcohol

1634 and 1635—A comparison of the Use of Alcohol and Gasoline in Farm Engines by Prof Charles E. Lucke and S. M. Woodward

1636 and 1637 The Manufacture, Denaturing and the Technical and Chemical Utilization of Alcohol are ably discussed by M. Klar and F. H. Meyer, both experts in the chemistry and distillation of alcohol Illustrations of stills and plants accompany the text

1611 and 1612—The Sources of Industrial Alcohol, that is the Farm Products from which alcohol is distilled, are enumerated by Dr. H. W. Wiley, and their relative alcohol content compared

1627 and 1628—The Distillation and Rectification of Alcohol is the title of a splendid article by the late Max Maercker the greatest authority on Alcohol Diagrams of the various types of stills in common use are used as illustrations

1619—The Uses of Industrial Alcohol in the Arts and in the Home are discussed

Any single number of the *Supplement* will be sent for 10c by mail. The entire set of papers above listed will be mailed on receipt of $1.90

Sensitive Laboratory Balance

By N. MONROE HOPKINS.—This "built-up" laboratory balance will weigh up to one pound and will turn with a quarter of a postage stamp. The balance can be made by any mechanic skilled in the use of tools, and it will work as well as a $125 balance. The article is accompanied by detailed working drawings showing various stages of the work. This article is contained in Scientific American Supplement, No. 1184. Price 10 cents. For sale by Munn & Co., Inc., 361 Broadway, New York City, or any bookseller or newsdealer.

YOUR INVENTION Made and Marketed

WE are looking for a reliable household, farm, automobile or novelty article which will meet a steady demand. If you have such an article it will pay you well to get into immediate touch with us. Manufacturing at minimum cost coupled with effective selling methods make our proposition exceptionally desirable. Either contract or generous royalties for the right man. We must have full details in your first letter.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full replies to correspondents are printed from time to time and will be mailed on request.

(12526) C. H. K. asks: 1. It is held I think by most astronomers that the pole of the heavens traces a complete circle around the pole of the ecliptic in about 25,000 years, and has for its center the pole of the ecliptic. There is also a decrease in the obliquity of the ecliptic of about 45 seconds in a century. Now, how can the pole of the ecliptic be the center of the circle traced by the pole of the heavens when the distance is gradually decreasing between them? As the obliquity of the ecliptic is equal to the radius of this circle, we would then have a circle in which the radius is constantly changing, which I think is quite impossible. A. In an exact sense it is true that a curve with a radius which varies cannot be a circle, as you say; but since the obliquity of the ecliptic changes only a few seconds in 100 years, while the precession of the equinoxes is about 50¼ seconds in one year, the change in the radius of the precessional effect on the pole of the heavens is at most infinitesimal in one year. We think astronomers are quite warranted in speaking of the motion of the pole of the heavens as in a circle around the pole of the ecliptic, although some use the latter term "cycle," since the variation in the obliquity of the ecliptic is also in a cycle. At some remote time it will return to its present value. 2. What was the obliquity of the ecliptic in 1900? A. The obliquity of the ecliptic for 1900 was 23 deg. 27 min. 8.02 sec., as given in Todd's "New Astronomy," page 150, a book which we send for $1.50. 3. Is there any evidence to show that an individual organism has the power to modify itself physically to meet a change in environment or meet conditions to which it is not adapted? A. Probably an individual organism has not the power to modify itself radically to meet a sudden change of environment to which it is not adapted. 4. Is there anything to show that evolution takes place apart from natural selection? A. All the causes of change in species and individuals and not natural selection alone are involved in the proof of the theory of evolution. The literature of the subject is very extensive, beginning from Darwin's "Origin of Species," which we will send for $2. Many articles have from time to time been printed in our SUPPLEMENT.

(12527) R. A. S. asks: What is the astronomical name of the star which is known as the star of Bethlehem, which guided the shepherds and the wise men at the birth of Jesus Christ and can be seen in Palestine every year on and about December 25th? A. There is no star known to astronomers as the "Star of Bethlehem." 2. Would a postage stamp vending machine pay? In the large post offices a great deal of time and bother is taken in handling and selling special stamps. Would it not pay the Government to have machines in the large cities eliminating this trouble? A. There are several kinds of stamp vending machines in the large cities, both in America and in Europe. We do not know whether they are profitable or not. 3. What are the advantages of raising the "Maine"? Does it not cost more to raise it than the old hull is worth? A. The raising of the Maine clears a dangerous obstruction from a friendly harbor, enables us to give burial to the bodies of the men who died in the service of their country on this ship, and may clear up the uncertainty as to the cause of the explosion. Any one of these reasons is quite sufficient to justify the expense of the work. The old hull is worthless. It was long ago corroded by salt water, and was so twisted by the explosion that it could not be rebuilt to be of any value. Its only pecuniary value would be as old metal.

(12528) J. C. O. says: Regarding a differential gear on an automobile using say 10 horse-power. A. claims that if standing in a straight line the same amount of power is applied to both drive wheels, but that in turning a corner the power is shifted to the outside drive wheel and that if it were required practically the full (40) horse-power would be exerted on this outside driver. B. claims that in making the turn as much power is exerted on the inside driver as on the outside. In other words (if it were required) 20 horse-power on each driver. Which is correct? A. The driving gear of automobiles is designed to exert an equal turning movement on each driven wheel at all times. If an automobile could be steered so sharply to one side that one rear wheel stood still while the other turned around it in a circle (this might be done by a three-wheeled car) the stationary wheel would be pulled on by the gearing just as hard as the moving wheel; but as it could not turn no "work" would be done upon it, and the "work" of turning the car would be done by the moving wheel entirely. Do not confound *force* with *work*; the latter implies motion in the direction of the force which produces it.

NEW BOOKS, ETC.

THE PRINCIPLES OF INDUSTRIAL MANAGEMENT. By John C. Duncan. New York; Appleton & Co., 1911. 338 pp. Price, $2.

The book is divided into three main sections devoted respectively to "The Economic Environment," "The Equipment of the Plant," and "Organization and Management." It deals on broad lines, and yet in considerable detail, with the various factors upon which the economic success of an industrial enterprise depends. The theory of industrial location, the different forms of "business concentration and integration," and the *rationale* of business specialization are some of the topics discussed in the first part of the book. The first three chapters of the second part follow a classification of the various industries as "synthetical," "analytical" and "assembling industries," a number of specific examples of each kind being given. As regards questions relating to plant equipment. Other topics taken up in this portion of the book are "Fire Precaution", "The Building," especially in its relation to the workers and "The Power Problem." The last section discusses the different types of organizations, the labor force and the methods of keeping records of work, equipment, raw materials, etc., and controlling expenditures in wages and purchases respectively. The subject with which Prof. Duncan deals is one of the greatest practical interest and will appeal to all who take any share in industrial work.

MOEURS DES INSECTES. By J. H. Fabre. Paris: Delagrave, 1910. 271 pp.; 12mo.

This volume is a selection of essays from the author's "Souvenirs Entomologiques." These delightfully written essays in a popular vein have been widely circulated in France, as they justly deserve to be. They are literature of a most artistic kind, even though the subject is scientific.

SKETCH OF A COURSE OF CHEMICAL PHILOSOPHY. By S. Cannizzaro (1858). Alembic Club Reprints. University of Chicago Press, 1911. Price, 43 cents.

To the person who has once acquired the habit of viewing the main facts of modern science in close relation to their historic development, this standpoint acquires a special value which is more easily appreciated than explained. The growth of a science is itself a natural phenomenon of peculiar interest, and probably no one ever has made himself the master of any branch of science, who did not in the process acquire a fairly complete knowledge of the genesis and history of that science. The consultation of first hand sources as compared with the mere reading of textbook reproductions, has, upon the student, an influence some what akin to that which personal contact with the great workers in science exerts. These things can be felt, but are difficult to analyze and explain. That they have been keenly felt by some of the foremost men of science is the cause of the publication of such series of reprints of classical scientific papers as the Alembic Club Reprints in English, and Ostwald's Klassiker in German. To express commendation of such publications, in view of the great authorities who have not merely passively approved of them, but actively aided in their realization, would seem almost presumptuous, and is at any rate quite unnecessary. That the present little volume should form one of the series is a fitting starting point. In it Cannizzaro presents with the masterly method of a great teacher the fundamental facts which form the basis of Avogadro's hypothesis. It must be remembered that while this hypothesis had been put forward as early as 1811, more than forty years prior to the date of Cannizzaro's work here republished, very little notice had been taken of Avogadro's law, and its immense importance to chemistry was not realized. Without this hypothesis a rational system of atomic weights was impossible, chemical notation was in a bewildering state, and the proper interpretation of all those relations between elements, which are closely connected with their atomic weights, was rendered extremely difficult. It is hardly possible to overestimate the importance to the chemical world of Cannizzaro's influence in bringing about the general appreciation of Avogadro's hypothesis. The little book should be in the library of every teacher of chemistry.

THE PRINCIPLES OF MACHINE WORK. By Robert H. Smith. Boston: Industrial Education Book Company. 8vo.; 388 pp., 434 illustrations. Price, $3.

This textbook, which takes up the subject where "The Elements of Machine Work" dropped it, admits technical students into the secrets of engine and speed lathes, drilling and grinding machines, steel cutting, measuring, turning, fitting, threading, chucking, reaming, jigs, fixtures, and cylindrical grinding. Mechanisms, tools and their approved methods of use are shown in original perspective and mechanical drawings while condensed tables briefly describe them. The common machining operations, with typical problems, are given in schedules which name the material, processes, machines, speeds, feeds, jigs, fixtures, and tools. As a guide to the young student of shop apprentice the work should prove invaluable.

MODEL NO. 3
The Kellner Equatorial Star Finder

Height, 10½ in. Adjustable to latitude.

The new model is now ready for delivery. This is the first star finder that points directly at the stars. Less than a year on the market it is already used by most of the large universities in U. S., however, especially intended for and adopted to the amateur astronomer. The price of the new model is $10, express paid. Money refunded if not satisfied. Send for circular.

C. J. Kellner, 305-W University Pl., Syracuse, N.Y.

A PLAN for INVESTORS

We invite your inquiries regarding our plan for the purchase of Railroad and Industrial Stocks, whereby WE COMBINE Higher Income, Increase in Value, A Saleable Equity, on partial purchases of active listed securities.

We will send, you upon request description of this plan, which is superior to buying stocks upon partial payments without eliminating partial payment advantages.

The Heavens in September

(Concluded from page 208.)

when she rises a little earlier than Mercury. On the 24th the two planets are in conjunction; that is they are as close to one another as their apparent paths allow; but in this case their distance is unusually large—over nine degrees—Mercury being the farthest north.

Mars is in Taurus, between the Pleiades and Aldebaran in the middle of the month, and rises about 9:30 P. M. Though only about half as bright as he will be at opposition in November he is already a very conspicuous object.

Jupiter is evening star in Virgo, and sets a little after 9 P. M. on the 15th Saturn is in Aries, approaching opposition and rises at about 8:45 P. M. on the same date.

Uranus is in Sagittarius and comes to the meridian at 9:10 P. M on the 1st and 7:16 on the 30th. Neptune is morning star in Gemini, rising about 1 A M in the middle of the month. The Moon is full at 11 A. M. on the 6th, in the last quarter at 1 P. M. on the 15th, new at 9 A. M. on the 22d, and in her first quarter at 6 A. M. on the 30th. She is nearest us on the 17th, and farthest away on the 1st, and again on the 29th.

She is in conjunction with Uranus on the 4th, Saturn on the 13th, Mars on the 14th, Neptune on the 17th, Mercury and Venus on the morning of the 21st, and Jupiter on the night of the 25th.

At 11 A M on September 23rd the sun crosses the celestial equator, entering the sign of Libra, and, in the old phrase, still used in almanacs, 'autumn commences"

How Animals are Taught Their Tricks

THE training of animals, to teach them to perform all sorts of entertaining tricks, is a task that requires perhaps a special talent on the part of the trainer, but above all demands patience and a thoroughly methodical procedure. Let us begin with the dog, and see how he is taught his tricks. We commence with the simplest, and gradually work up to the most complex and apparently impossible feats

The first thing every dog must learn is his name Select a short, sharp-sounding name, and stick to it. Never call him anything else If you have several dogs, the name is taught on the same principle Divide their food, and then, placing a piece on the ground, call each in turn by his name, and give him the food when he comes for it. Send the others back if they come forward out of their turn. By and by they will learn that a certain name is always associated with a certain dog. Ramble among the dogs, and call out one of their names every now and then. If the right dog comes to you, reward him with a piece of cracker Pay no attention to the other dogs. They will learn very soon; and the first great lesson—dependence and obedience—will have been learned

Having taught a dog to fetch and carry —which he will easily learn—the next thing is to teach him to go and get any object called for Place a glove on the floor; then say to the dog, "Fetch the glove," putting the accent on the last word. Then, when he has done this several times, place a shoe on the floor; and teach him to fetch this in a similar manner Now place both objects on the ground, and teach him to fetch either one, as asked for—rewarding him when he brings you the right one, and rebuking him when he fetches the wrong, which you take from him and replace. He will soon learn to distinguish the articles, when a third may be substituted, and so on until a number are on the floor. You should then go into the next room, taking the dog with you, and send him in to fetch any article you mention. After a little time, he will bring you the right one every time.

Next, teach him differences in color. Place a red object on the floor, and a blue one beside it. Teach him to fetch you the article called for as you did before, being careful to reward him every time he brings you the right handkerchief. Then put down a green object, a purple, a yellow one, and so on; until finally the needed array of colors can be placed for selection.

Next, he should be taught the articles of furniture—table, chair, etc. He must go to each one as you call out its name Finally, combine some of the previous commands "Place the glove on the chair", "Get the handkerchief, and place it on the table," etc. At first this should be said very slowly, and only half the command repeated at once; but the halves of the sentence may be gradually blended together, until you can say it as you would to any individual; and the dog will obey your command.

To a certain extent, also, dogs may be taught the letters of the alphabet, the numbers of spots on cards, large dominoes, etc The method of training them is simply one of constant repetition Cards bearing the letter or number are placed in front of the dog, and the letter or number is called out aloud, and at the same time the dog is shown which one it is. After several trials, he will select this one and disregard the others, when it is called for This once learned, the next letter is taught in like manner, until a large number are recognized by the dog, and he is able to pick out any of them at will Plants are also to be selected in a similar manner, from a row placed on the table, and so forth

It must be admitted, however that most feats of this character, as performed in public, are the result of some trick, rather than any marvelously elaborate training on the part of the dog which would be necessary if these feats were genuine—granting them to be possible at all As a matter of fact, most of these apparently marvelous feats are based on a very few cues, given to the dog at the appropriate time, to which he has been taught to respond in a simple manner. A few examples will make this clear

Many of these feats are performed by means of a cue word, in just the same kind of way as "mind readers" entertain and puzzle their audience As soon as this word is given, it may be in the course of a sentence, the dog knows that he is to perform a certain action It is not necessary for him to understand the whole of the sentence; only one word in it As soon as that word is caught the action is performed Each action corresponds to a certain cue word. Again, there is the method of training by the use of the eyes. The dog watches his master's eyes, and when his master glances in any direction—at a card, for example—the dog can follow his glance, and pick out the card in turn Or the dog may be told to bark a certain number, in which case the dog watches his master's face closely, and simply barks until the eyes, or some movement, tell him to stop He does not have to know that he barks nine times. All he has to know is that he must go on barking until he is told to stop by his master's signal, and the trainer is the one who does all the counting

There are certain stage tricks which depend very largely upon the dog's memory, however—such as picking up a numbered card, and the like The cards are arranged in a row, and the trainer stands in front of the row in which the card rests. A string is attached to the dog's neck First the dog is trained to go to the row of cards nearest the trainer; then, if he is inclined to pick up one too near, a slight pull on the string is given, pulling the dog up to the required number The trainer stands at a certain distance from the table in these tricks, if close to the table, the dog knows it means card one; if farther away, card two, and if still further, card three By care in training, the dog can be taught to pick out any required card, without in any way knowing the number written upon it When the dog has been taught to pick up any card by means of this code, the trainer may appear to make it far more complicated by causing the dog to add, subtract, multiply, divide, etc. All that is necessary, of course, is that the performer himself should do the sum, mentally note the position of the card giving the answer, and indicate this card to the dog by means of some hidden code.

In the same way, horses can be made to stamp out any desired number, tell the date of a coin, etc., by simply going on pawing the ground until the trainer gives them the signal to stop by means of some secret sign, unnoticed by the audience.

Every man who puts on a von Gal made hat has something more than a fine hat. He wears a permanent guarantee of satisfaction. This is the one hat that must be to your liking. The fit—the material—the style—the wear—all must be what you pay for. Your dealer guarantees it to you—we guarantee it to him. Do you wonder at the strong trend of public favor that has given to

HOW TO BUILD A 5 H.P. GAS ENGINE AT HOME

In *Scientific American Supplements*, 1641 and 1642, E F Lake describes amply and thoroughly how a five horse power gas engine can be built at home Complete working drawings are published, with exact dimensions of each part ¶ Price by mail for the two Supplements, Twenty Cents ¶ Order from your newsdealer or from

MUNN & CO., Inc., PUBLISHERS, 361 BROADWAY, NEW YORK

The reason why—

the Scientific American holds its old readers and is gaining in circulation so rapidly is that it is *interesting* We recently asked our subscribers to send us the names of people whom *they* believed the Scientific American would interest and the "interestingness" of the magazine is demonstrated by the large number of the names so received which have been added to our regular subscription list. Have you sent us a list? If not

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest. An accurate record of all names received in this manner will be kept, and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send

Address all lists to the Circulation Department, Scientific American, 361 Broadway, New York.

As to the animals which perform in the circus, the elephant is among the most popular, and it seems wonderful that so unwieldy an animal can be made to perform any tricks at all. How set about training an animal of this kind? What is the first thing to be done? And how?

In compelling the elephant to perform, advantage is taken of the fact that the feet of the animal are peculiarly sensitive and he dreads any injury to them. Many of his tricks are based upon this principle Thus, he is made to place one foot upon a low pedestal; then the other foot is tapped gently, and he raises this and places it beside the other—to get it out of harm's way. The hind feet are treated similarly, in turn—the front feet being hit every time they are placed on the ground In this way all four feet are finally placed upon the tub The trick of inducing an elephant to partake of a meal is very simple Animals will naturally eat anything placed before them, and it is only necessary to open a bottle of "pop" once or twice, and present it by hand, when the animal may be trusted to find out for himself how to get at its contents In all such cases, the essence of the training consists in infinite patience, kindness, and constant repetition—showing the animal over and over again how a thing is done—in precisely the same way—and then forcing him to do it himself

Lions and tigers are always dangerous creatures to work with, and one can never be sure of them, even when trained "No wild animal," says Mr Bostock, "is ever tamed, only trained, and the best training in the world is nothing when once the animal feels inclined to give way to his natural savage instincts"

"In time," continues Mr Bostock, "the trained animal becomes so accustomed to performing that when he sees the paraphernalia of his performance he knows exactly what is expected of him, and does it naturally and readily The successful performance of all trained animals depends on this almost instinctive following of long-accustomed habit, together with the pleasure the exercise gives to animals habitually confined in small cages

"Leopards, panthers and jaguars are all trained in much the same manner Mme Morelli puts them through a course of training very similar to that given the lion They are taught to respect and look for the trainer, and have instilled into them as much awe as is ever bred in any animal—which is not saying a great deal Some animals train easily, others learn their lessons with great diffidence and some reluctance What one lion may learn in a week another may learn in a month; what one tiger may do in two lessons may take another one several months to imitate feebly"

Goats are very sure-footed animals, and learn to perform many tricks requiring that quality—such as standing on the end of a bamboo pole The Hindus teach goats to do this Hogs may be taught a number of clever tricks, and are far more intelligent than is generally imagined Monkeys are known to be capable of being trained to a remarkable degree, the feats of "Peter" and "Consul" being well known to the American public They are good imitators, and excessively curious, and it is this faculty, and their ingenuity in satisfying this curiosity, which has amused many an audience; and has given rise to the popular notion that monkeys are far more intelligent than they really are As a matter of fact, although a few of them are highly trained and intelligent, this is not the general rule

A few birds may be trained to perform simple tricks, but not many "Fortune tellers" employ tame birds to help them in their trade A number of small paper envelopes are seen, in a row, one of which contains your "fortune" In the shape of a slip of paper, telling you certain platitudes about yourself. The bird picks this envelope out with his bill, from among others How is it he selects this particular one? Some of the envelopes have seeds glued to their back covers, and the bird naturally picks out one which has the seed thus attached—passing over the others to get to it. In most birds, when first caught, a portion of the inner plume of the pen-feathers is cut, so that the bird cannot escape; and then the nostrils of the bird are touched with bergamot or other odorous oil, by which it is for the time so stupefied that it perches quietly on the finger. It is then taught to hop from one finger to another. In this way its training is begun.

Snakes are trained by the natives of India, and no other nation has succeeded in reaching so high a degree of efficiency as these East Indians. The fangs of the snake are first extracted, so as to render it harmless; it is fed on milk, and more or less drugged a good part of the time—as are many other animals which perform in public. The peculiar character of the native music seems to hypnotize the creatures, which, under its influence, emerge from their baskets and are handled with seeming impunity by the natives

Seals are very intelligent animals—despite their looks—and may be taught a number of tricks of an intricate character—tricks requiring a delicate sense of balance and manipulation. Kangaroos also may be taught to box and wrestle with their trainers, and in many ways make excellent performers

The Current Supplement

A SERIAL article from the authoritative pen of Prof H. H Turner, of Oxford, England, begins in the current issue, No 1861, of our SUPPLEMENT The eminent astronomer gives a most interesting account of the history and function of the Great Star Map, in the preparation of which workers all over our globe are taking part —This issue also brings the sixth instalment of Donald Murray's article on Printing Telegraphy —Major Bartlett continues his most interesting discussion of "Logistics," and the problems that arise in taking care of the bodily needs of an army in the field —In an article on "The Dawn of Architecture" Mr John L Cowan brings before us a vivid picture of the first steps in the evolution of human dwellings.—A very remarkable and extremely delicate new test for adulteration of oils with mineral or resin oils is described by A E Outerbridge, Jr —Much has been said and written in late years of the gyroscope and its intentional application to various purposes That gyroscopic effects appear as untavited guests in machinery is a fact which has to be reckoned with on aeroplanes for example This subject is lucidly presented by Mr A Kapteyn —A number of clever "Household Inventions" are reproduced from *La Nature* —Mr E L Thorndyke suggests an ingenious method of quantitative measurement for the quality of literary style, which he applies primarily to the performances of school children.—The mind stands aghast before the figures which must be used to represent the dimensions of some of the objects which the modern physicist measures with comparative ease and certainty. Not so very long ago it was thought a remarkable achievement of the human mind when a numerical estimate of molecular dimensions was gained. Now we have the electron, whose mass is about one eighteen-hundredth of that of a hydrogen atom Prof Pyle of Washington University gives a vivid account of these modern developments.

The German Artificial Sponge

AN artificial sponge, the outcome of German ingenuity, is now to be had. The process of making it consists principally in the action of zinc chloride on pure cellulose This results in a pasty, viscous mass, which is mixed with coarsely grained rock-salt

Placed in a press-mold armed with pins, the mass is pierced through and through until it appears traversed by a multitude of tiny canals, like the pores of a natural sponge The excess of salts is subsequently removed by prolonged washing in a weak alcoholic solution. The artificial sponge swells up with water, but hardens on drying, just like its prototype; it is said to be eminently adapted for filtering water for sanitary or industrial uses, and it can be employed for all the purposes that are usually assigned to the genuine article.

Valuable Books

The Scientific American Cyclopedia of Formulas

Edited by ALBERT A. HOPKINS. Octavo, 1077 pages, 20,000 Formulas. Cloth, $5.00; Leather, $6.00.

This valuable work is the result of many years of labor and research, and contains about twenty thousand of the most useful formulas, compiled from the best sources at home and abroad. It has been prepared with the object of placing before the public a book containing a large number of valuable formulas, which are not to be found in any other publication, and which are of such a character as to make it a useful and indispensable companion. It is a work for the practical every-day man in the workshop and home.

Handy Man's Workshop and Laboratory

Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations. Price, $2.00.

This is a compilation of hundreds of valuable contributions and suggestions by many of the most handy men in the mechanical and scientific lines. A book of this sort does not pretend to be original, as the best collection of ideas of the most skilful mechanics and scientists would be of little value if they were published in the form of textbooks. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.

Concrete Pottery and Garden Furniture

By RALPH C. DAVISON. 12mo., 196 pages, 140 illustrations. Price, $1.50.

This book describes in detail in a most practical manner the various methods of manufacture of concrete pottery and garden furniture. A little more than a year ago, concrete, commonly known as cement, was used for the construction of the heavier forms of garden furniture, such as settees, tables, vases, fountains, and similar articles. Now there are shown in the stores, in the book, many handsome designs of these and many other forms, including the smaller forms, like vases, and flower pots, suitable for the indoors. With the methods given in the book, any handy man or farmer can make many useful and ornamental objects to ornament the indoors, most of the home or garden. The information on color work alone is worth many times the cost of the book.

The Design and Construction of Induction Coils

By A. FREDERICK COLLINS. Octavo, 295 pages, 159 illustrations. Price, $3.00.

This work gives in minute detail full practical directions for making each different form of induction coil, and also gives a good deal each regard to a large one giving twenty-inch sparks. The various parts of the coil are each taken up in order, and the proper way of making them described in full. The proper methods for winding the primary and secondary coils, making the condenser, the vibrator, the spark gap, the secondary discharger, and the various other parts of the coil are described in detail. Much of the matter in the book has never before been published, as, for instance, the best methods of winding and impregnating armatures, the making of experimental induction coils, the use of the Wehnelt electrolytic interrupter, the construction of a 100-inch spark coil, the theory of the induction coil, the various methods of winding alternating coils, etc. The illustrations are all from original drawings, which were made especially for this work.

Industrial Alcohol Its Manufacture and Uses

By JOHN K. BRACHVOGEL, M.E. Octavo, 328 pages, 107 illustrations. Price, $4.00.

This is a practical treatise, based on Dr. Max Maercker's Handbuch der Spiritusfabrikation, as revised by Dr. Delbrück and Lange. It contains complete directions for the selection, erection and operation of machinery, buildings, and power required for the economical production of industrial alcohol and motor spirit. Particular attention is given to the subject of fermentation, the various methods of distillation, the use of a test-room laboratory, denaturing, the handling of grain, beet and potato products, a statistical review and the United States laws. This is one of the most comprehensive books issued on the subject and is based upon the researches and practice of the most eminent of Germany's specialists in the manufacture of industrial alcohol and its application to commercial uses.

Home Mechanics for Amateurs

By GEORGE M. HOPKINS. 12mo., 370 pages, 330 illustrations. Price, $1.50.

This is a thoroughly practical book by the most noted power and mechanic in America. It deals with useful subjects about which the average mechanic knows little or nothing. It tells how to make electrical apparatus, including electric bells, telephones, batteries, electrical engines, dynamos, motors, etc. It tells how to make electric lights, and how to install them. It tells how to make and operate wireless telegraph apparatus. It tells how to make and operate electric toys, and numerous other things of interest to every boy and man. It tells how to make them in such a way as will be the most simple manner and the least in dollars. Many the right way, and simple manner.

Any of these books will be sent, postpaid, on receipt of advertised price

Electricity

Some Recent Developments in Railway Telephony.—The telephone has been found to possess advantages over the telegraph on railroads, and it is stated that on about 37,000 miles of road the former has now been adopted without any accident having been attributed to its use. This change has been made within the last four years. The three main classes of service performed by the telephone are (1) train despatching, (2) message service, and (3) block-wire service.

Mercury Contact for Railroad Signals.—A novel contact for railway signals has recently been designed, which obviates the necessity of energizing the rails themselves in order that the circuit may be closed by the trucks of the passing trains. The device consists of a treadle secured to the under side of a rail between the points of support. As the rail is flexed under the weight of a passing load, it presses a plunger downward against a diaphragm covering a chamber filled with mercury. Owing to the area of the diaphragm, a very slight depression causes a considerable rise in the column of mercury at one side of the chamber. The mercury thus closes the circuit of the electric signal.

Novel Fan for Dining Tables.—It is always difficult to break away from old ideas. The disk type of electric fan has shown no marked change in design since the day it was first introduced. It still throws a stream of air in a single direction and in order to distribute the cooling effect of the fan to better advantage, various schemes have been devised such as turning the fan bodily or shifting direction vanes before it. An entirely new scheme has now been evolved in which the fan is radically altered. This fan throws a centrifugal zone of air. It is mounted on a vertical shaft and its blades are also vertical, giving it a cylindrical form. As this revolves, it sucks in air from the top and bottom and throws it out centrifugally. A fan such as this placed at the center of a dining table serves to cool all the diners uniformly.

Double Antennae for Determining the Direction of a Transmitting Wireless Station.—If two identical antennae are placed a small distance apart as compared with their common distance from a transmitting station, they perform identical oscillations, so far as amplitude of current and voltage is concerned, but the current and voltage are displaced with regard to each other by a phase difference depending on the distance between the two antennae and the angle which the line joining the same makes with the direction of propagation of the waves. An arrangement consisting of two antennae and two phase meters can therefore be used to ascertain the direction from which the incoming wave is being received. An installation of this kind has been described by Mr. Petit in *La Lumière Electrique*, as is noted in a recent number of the *Génie Civil*.

Aluminium Coils in Traction Motors.—Considerable interest was shown at the International Congress at Brussels, in a paper on the subject of using aluminium in place of copper for the field coils of street railway motors. A number of cases were referred to in which such coils had been in use for several months. In some instances the wire was insulated with rubber, in others with lacquer, while in still others bare aluminium wire was used, the aluminium oxide serving as sufficient insulation between turns, while paper, cloth and the like, were used between layers. The advantages claimed for aluminium, are that it saves 50 per cent in weight for the same resistance, and, in view of the fact that there is a larger volume of aluminium in a pound than of copper, there is a saving of about 50 per cent in the cost of the material. Another thing to be considered in the fact that aluminium coils are much lighter, and hence make a smaller load for the motors to carry, and are less affected by vibration and shock. Furthermore increase in temperature is less destructive because less or no insulation is used. To offset these advantages aluminium coils must have a larger cross-sectional area, and the metal is exceedingly difficult to solder.

Science

Prof. Kossel in the United States.—Prof. Albrecht Kossel, of the University of Heidelberg, arrived recently in this country for the purpose of delivering a series of lectures at Johns Hopkins, and other American universities. Prof. Kossel was awarded the Nobel prize in 1910 for his researches in medical chemistry.

Wireless Weather Reports from Gibraltar.—We learn from *La Nature* that wireless weather reports are now sent every morning from Gibraltar to the Meteorological office in London. The dispatch is copied, en route, at the Tour Eiffel in Paris and promptly sent to the headquarters of the French meteorological service, which includes it in the daily weather bulletin. The use of wireless telegraphy in meteorology is rapidly growing, despite the discouragements that attended the earlier attempts in this direction, and is clearly destined to greatly facilitate the methods of weather forecasting.

Cleaning Cleopatra's Needle.—The Egyptian obelisk which is known as Cleopatra's Needle, which stands on the Thames Embankment, is being cleaned for the first time in its history. For centuries it stood in its native land and never needed the brush. London soot and fumes have begun to mar the face of the obelisk. The obelisk in New York has been protected for years by means of paraffin, in accordance with a method devised by the late Prof. R. Ogden Doremus. London seems to be baffled by the same problem. There seems to be no reason why the Doremus method would not apply.

Loess.—The formation of "loess," a fine yellowish sandy clay found in various parts of the world, and reaching a thickness of over a thousand feet in China, has given rise to much discussion and controversy among geologists. The presence of the shells of snails that feed on plants indicates the former presence of plants. Accordingly it has been suggested that the genesis of these remarkable deposits may be fully accounted for by wind action, coupled with the growth of plants which have caught and compacted the blown dust and sand in the way that sand dune plants do at the present day on our seashores.

The Winds in the Free Air.—In the *Annals of Harvard College Observatory*, vol 68, pt 2, Mr Andrew H Palmer, research assistant at Blue Hill Observatory, publishes a discussion of "Wind Velocity and Direction in the Free Air," based on a great number of kite, *ballon-sonde*, and cloud observations, chiefly at Blue Hill. Comparisons of the wind conditions at various altitudes above the earth's surface are timely, in view of their great interest to the aeronaut. The general principles brought out are: (1) The general increase in velocity with height; (2) the rare occurrence of gusts of wind above low heights; (3) the frequent clockwise and the occasional counter-clockwise change of direction with height; (4) the shallow character of easterly winds (at Blue Hill); (5) the relative frequency of ascending currents as compared with those descending.

The Sizes of Rain Drops.—At a recent meeting of the Royal Meteorological Society Mr Spencer Russell gave an account of the experiments that he has carried out at Epsom during the past two years to obtain a permanent record of the variations in the size of rain drops as they occurred. The first method employed was the exposure of a number of level plates, divided into quarter-inch sections, and gently brushed over with an even coating of oil. It was found, however, that in a heavy rain the drops striking the slate were broken up into a series composed of one large and several smaller ones. A more satisfactory method was that of letting the drops fall into dry plaster of Paris. Mr. Russell exhibited to the society a number of models of rain drops obtained in this manner. He stated that of the drops so far collected the diameters were as follows: 7 of 6 mm., 44 of 5 mm., 73 of 4 mm., 222 of 3 mm., 257 of 2 mm., 175 of 1 mm., and 107 of less than 1 mm.

Cadillac progress

in scientific research marks a well defined line between the motor car of the past and the motor car of now.

Automatic electric starting device. Electric lights. Two complete ignition systems. Scientifically developed carburetor. More power. Larger wheels and tires. Larger brake drums. Steel bodies of latest accepted designs. Numerous refinements of essential details.

The improvements incorporated in this year's specifications will give a pronounced impetus to the conditions which have constituted the Cadillac *a law unto itself*

These improvements are obviously the result of an economic and evolutionary development, hence, it is useless to seek them elsewhere

They are the fruits of Cadillac research; of close and accurate measurement; and of *scientific standardization*

Consider what an augmentation of comfort is implied in these two announcements emanating from the Cadillac Company, which has never promised what it did not fulfill—

First. A surpassingly fine car made infinitely finer, and Second, a hitherto unattainable ideal resolved into a practical reality.

This more refined and efficient car, is a product of that process of ceaseless progress toward perfection, which has prevailed in the Cadillac plant for ten years

The simple, centralized, Delco system of starting, igniting and lighting is merely a phase, or *an integral part of that process.*

To combine these elements of efficiency, for the first time, in a unit, exercising the three separate functions, is of itself an interesting achievement, although such a system as an adjunct to an indifferent car, would be of doubtful value

But to combine them in the Cadillac adds lustre to that achievement, because it *endows an extraordinary motor car with new and beneficial indispensable functions*

Without them, the Cadillac would still be the incarnation of ease, grace, elegance and economy

With them, a new meaning attaches to the word luxury as applied to motoring

The 1912 Cadillac automatically removes itself from the realms of competition

CADILLAC ELECTRICAL SYSTEM

Starting Lighting Ignition

The electrical plant in the new Cadillac not only accomplishes what heretofore has been accomplished in a less efficient manner by separate systems—ignition and lighting—but goes further and includes in its functions a feature to which motorists have long looked forward, an automatic starter which obviates the necessity of cranking by hand

The plant consists of a compact and powerful dynamo operated by the engine of the car The dynamo charges the storage battery

For starting the engine the dynamo is temporarily and automatically transformed into a motor, the current to operate it as a motor being furnished by the storage battery

To start the engine, the operator, after taking his seat in the car simply presses the spark lever and pushes forward on the clutch pedal This automatically engages a gear of the electric motor with gear teeth in the fly wheel of the engine, causing the latter to turn over thereby producing the same effect as by the old method of cranking As soon as the engine takes in charges of gas from the carburetor and commences to run on its own power the operator releases the pressure on the clutch pedal the electric motor gear disengages its connection with the fly-wheel and the car is ready to be driven The electric motor then becomes a dynamo or generator and its energy is devoted to ignition and to charging the storage battery

The storage battery has a capacity of 80 ampere hours and as soon as that capacity is reached, the charging automatically ceases

Practical tests have shown that the storage battery is of sufficient capacity to operate the starting device and turn over the engine about twenty minutes, although it seldom requires more than a second or two in fact the Cadillac engine so frequently starts on the spark that the use of the electrical starter is not always required

The storage battery also supplies the current for lighting The car is equipped with two especially designed Gray & Davis electric head-lights with adjustable focus two front side lights tail light and speedometer light

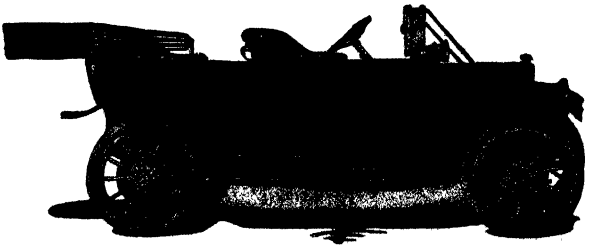
The dynamo also supplies current for ignition Up to 200 to 600 R P M the ignition current comes from the storage battery above that speed the current is direct from the dynamo through the high tension distributor to the spark plugs For ignition purposes the dynamo performs not only all the functions of the most highly developed magneto, but possesses even greater efficiency having more flexibility and a greater range of action When compelled to drive slowly in crowded thoroughfares over very bad roads or on hills with the usual magneto, the driver may stall his motor because the magneto is not being driven fast enough to generate current and it becomes necessary to switch to the battery If he has one With the Cadillac system if it becomes necessary to drive so slowly that sufficient current is not generated the battery automatically cuts in When the speed is increased the dynamo again automatically takes hold It wholly obviates the necessity of the driver's keeping constantly on the alert to prevent stalling the motor

In addition to the ignition is fore described the Cadillac is provided with the auxiliary Delco system with dry cell current which has proven so satisfactory in the past The extra system is separate and distinct with its own set of spark plugs and in itself is thoroughly efficient for running the car, entirely independent of the main system

The entire electrical plant has been designed with a view to completeness and efficiency It is designed with the idea of simplicity and positiveness It is designed to obviate to the greatest possible degree the necessity of attention Above all, it does what it is designed to do

A few of the improvements in the 1912 Cadillac

Automatic electric starting device electric lights (See detailed description in another column)



Increased power resulting from motor refinements and our own new carburetor This new carburetor has not only simplified the matter of adjustments, but possesses maximum flexibility and maximum efficiency from low to high speeds without change of adjustment, excepting air adjustment controlled by small lever at the steering wheel.

Wheels and Tires Increased from 34 in x 4 in to 36 in. x 4 in

Brake drums Increased from 14 in to 17 in diameter

Bodies Steel, of latest accepted designs, all fore doors, constructed upon new improved methods.

Gasoline capacity Increased to 21 gallons on all models excepting Phaeton and Roadster, in which the increase is to 18 gallons Gasoline gauge on dash

SPECIFICATIONS IN BRIEF

MOTOR—Four-cylinder, four-cycle, cylinders cast singly, 4 1/4-inch bore by 4 1/4-inch piston stroke. Five-bearing crankshaft. Five-bearing cam shaft. **HORSE-POWER**—Nominal, A. L. A. M. rating, 32 6. Actual horse-power greatly in excess of this rating, due to Cadillac design. Cadillac principles and Cadillac construction **COOLING**—Water, copper jacketed cylinders. Gear driven centrifugal pump; radiator tubular and plate type. **IGNITION**—See description under Electrical System. **LUBRICATION**—Automatic splash system, oil uniformly distributed. **CARBURETOR**—Special Cadillac design of maximum efficiency, water jacketed Air adjustable from driver's seat. **CLUTCH**—Cone type, inner leather faced with special spring ring to fly wheel. **TRANSMISSION**—Sliding gear, selective type, three speeds forward and reverse. Chrome nickel steel gears, running on two annular ball bearings. Bearings oil tight **CONTROL**—Hand gear-change lever at driver's right, inside the car Service brake, foot lever. Emergency brake, hand lever at driver's right, outside. Clutch, foot lever Throttle accelerator, foot lever. Spark and throttle levers at steering wheel. Carburetor air adjustment hand lever under steering wheel **DRIVE**—Direct shaft to bevel gears of special cut teeth to afford maximum strength Drive shaft runs on Timken bearing. **AXLES**—Rear, Timken full floating type; special alloy steel live axle shaft. Timken roller bearing. Front axle, drop forged I beam section with drop forged yokes, spring perches, tie rod ends and steering spindles Front wheels fitted with Timken bearings.

BRAKES—One internal and one external brake direct on wheels, 17-inch by 3 1/2-inch drums Exceptionally easy in operation. Both equipped with equalizers. **STEERING GEAR**—Cadillac patented worm and worm gear, sector type, adjustable, with ball thrust, 14-inch steering post, 16-inch steering wheel with walnut rim; aluminum spider. **WHEELS**—36 inches. **TIRES**—36-inch by 4-inch Hartford or Morgan & Wright. **PAINT**—Fresh, hand-finished. Rear, three-quarter platform. **FINISH**—Cadillac blue throughout, including wheels, light striping, minor mouldings. **GRADE AND EQUIPMENT**—Dynamo with 80 A. H. battery for automatic starter, electric lights, and ignition. Two Delco distributor system. Lamps especially designed for Cadillac cars, black enamel with nickel trimmings: two headlights; two side lights, tail light; Prest-o-lite tank in rear; horn; full foot rail in tonneau; half foot rail in front; robe rail; tire irons; set of tools, including pump and tire repair kit; extra rim in all bodies except closed cars. Speedometer, standard, improved with 4-inch face and electric light.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

The "Oregon" a Prototype of the Dreadnought?

MUCH has been said and written, during this present era of big warships of the so-called dreadnought type, about the astounding but nevertheless continual increase in the size and power of armored ships; but it takes such a concrete presentment as is shown in our artist's comparison on another page of this issue of the old "Oregon" of the United States Navy and the new "Lion" of the British navy to bring home to our minds the amazing development which has occurred during the past twenty years.

Turn back to the newspaper files of the early nineties, in which the naval specialist of the daily press was struggling to express his sense of the almightiness of the "Oregon," and you will realize that there was a common belief that the limit of fighting power had been pretty well reached. And there was much ground for the prevailing enthusiasm; for in 1890, the date of the signing of the contract for the "Oregon," there was no ship afloat that compared with her in the weight of metal which could be discharged in a single broadside.

So great has been the advance in the intervening years that the "Lion," with her speed of from 28 to 30 knots and her battery of eight 13.5-inch guns, could meet the "Oregon" and her sisters, the "Indiana" and "Massachusetts," and sink them without running the risk even of serious disablement. With her superior speed, she could maintain a position so far distant, that the 13-inch shells of the older ships would reach her with a diminished striking energy that would be quite insufficient for penetration of her Simpson armor, while at that same range the obsolete armor of the "Oregon" and her consorts would be penetrable by the new 13.5-inch gun.

Comparing the old and the new in detail, we find that the length has gone up from 348 feet to 700 feet, the beam from 69.3 to 86.5 feet, and the displacement from 10,288 to 25,250 tons. The "Oregon" was propelled by reciprocating engines of 11,037 horse-power at a speed of 16.79 knots, whereas the turbines of the "Lion" will probably develop from 75,000 to 77,000 horse-power, driving the great ship at a speed of between 29 and 30 knots. The "Oregon" stowed 1,450 tons of coal in her bunkers; the "Lion" will accommodate 3,500 tons of coal and 1,000 tons of oil fuel. Although the armor on the sides of the "Lion" will be only about half as thick as that on the "Oregon," its resisting power, because of the harder and deeper face, will be greater.

This comparison is made without any thought of disparaging the qualities of the older ship. Indeed, it is worthy of note that the "Oregon" foreshadowed the original dreadnought and all the great ships which have followed her general plan. The European battleship of the early nineties carried four big guns as the main armament, and then dropped into the feeble five and six-inch guns as a secondary armament. The 8-inch, armor-piercing guns of the "Oregon" were a distinct innovation; and it is certainly but just to the naval designers of the United States navy of that day to credit them with having suggested the advisability of an all-big-gun armament as the best suited to the line of battle. The editor, indeed can remember more than one personal discussion of the subject with officers of our navy who protested against the elimination of the 8-inch gun from the "Maine" class of battleships, and urged that the substitution should have been rather of 10-inch guns than of 6-inch for the eights which were carried on the "Oregon."

"The World Patent"

IN speaking before the annual meeting of the Society of German Chemists last June, Dr. E. Kloeppel chose for his subject the "World Patent," and discussed the question of what could be done in Germany at the present time toward the ultimate realization of a universal patent of international validity. While it would be quite unreasonable to be at all optimistic with regard to the early realization in full of such an idea, the speaker pointed out that this is no reason why such steps as are within reach should not be taken to proceed at least some small distance in the direction toward the ultimate goal. Much of what Dr. Kloeppel said is of great interest to the inventor and patent lawyer, and some of the salient points of his address are outlined below.

Dr. Kloeppel first of all pointed out that when we speak of a world patent we tacitly limit our ideas to the countries of the International Union, which of course enter first into consideration. In this connection it is interesting to note a communication published by Damme, that the French government made a proposal at the diplomatic conference of the States of the International Union recently assembled at Washington, according to which all patent applications in the countries of the Union are to be registered at the Bureau in Berne. This plan would be easily carried into effect (as has already been done with regard to trade-marks), if all the countries of the Union followed the French system of patent application without preliminary examination. In view of this it is not surprising that the first detailed publication on the "World Patent" should come from the pen of an energetic opponent of a preliminary examination. Du Bois Reymond opens his book with the declaration that he would look upon a final victory of the preliminary examination process as a "victory of the irrational over the rational." Dr. Kloeppel himself does not follow Du Bois Reymond in this matter, though admitting that the latter's publication contains much which will help to create a receptive spirit toward the idea of the "World Patent," even though its full realization may be a very long way off.

Starting from this basis we may briefly examine what possibility there may be of simplifying the process of examination in connection with patent applications by the aid of international agreement. The chief problem here is to determine how far the actual work of examining, which under the present system is repeated in each country in which an application is filed, could be performed once for all by one country, and the results made available for use in dealing with the applications in other countries.

At the present time England, Austria, Portugal, the three Scandinavian States, Japan, Germany, and the United States have a preliminary examination. As a matter of fact, the objective treatment of the problem of examining differs much less even now in the several countries than is commonly supposed. It is not by any means true that the more important States have the most rigorous examination. Thus, the Scandinavian States have a very strict and thorough examination. Du Bois Reymond proposed that the unnecessary duplication of the examining labor be reduced by the establishment of closer treaties between the individual countries. For instance, the first step might be taken by Germany making an agreement with Austria that all German patents should without further parley be valid in Austria, and *vice versa*. There are, however, considerable difficulties in the way of such a plan, and in fact arrangements of this kind have existed in the past but have been subsequently abolished. The kind of trouble that would be likely to arise can be foreseen if we consider for example the fact that a given patent would be construed by German courts, while it could be set aside only by Austrian authorities.

Another plan which tends in a somewhat similar direction, but could probably be more readily carried out, is suggested by the following considerations:

At a time when Austria had not joined the Paris Convention, and the German-Austrian Treaty of 1891 was still in force, a joint applicant would, as a rule, wait until his German patent was completely examined and issued, and would then apply for a patent in Austria, receiving by the terms of the treaty the benefit of priority in accordance with the date of his German application. So far as can be ascertained, it hardly ever occurred that the Austrian Patent Office—which has a very rigorous examination—refused to grant such patents or even cited new matter against them. It may therefore be said that practically the Austrian Patent Office granted patents on the basis of the German preliminary examination. As a matter of fact, under present conditions, since Austria has joined the Paris Convention, and the German-Austrian Treaty of 1891 has been rescinded accordingly, considerable changes have taken place, and a German applicant is in general forced to file his Austrian application before his German patent is issued, in order to obtain the benefit of the twelve months allowed for priority rights by the Paris Convention. There appears to be no cogent reason why the admission of Austria to the Convention should set aside the previously existing treaty. This latter might therefore be renewed and a clause might be added which would obviate the duplication of the examining work. There would be no occasion for any solicitude that, for instance, the Austrian examination should be less stringent than that in Germany, for in practice this is found not to be the case; indeed, instances are known in which rather the reverse is true. Moreover, any possible error which might arise would be automatically corrected in the subsequent "Einspruchsverfahren" which forms part of the regular procedure both in Germany and Austria in the course of obtaining a patent.

If a treaty of this kind were made first of all between two countries such as Germany and Austria, which are closely related politically and in point of patent law, no doubt the desire would soon be felt among other nations to enter into similar agreements. Possibly when the advantages of such a plan become fully realized, other nations, whose patent laws differ more widely from those of Germany, might be persuaded to take similar steps.

The suggestions made by Dr. Kloeppel are of course framed entirely from the German point of view, and allowance must be made for this in considering them. Possibly, too, they may appear somewhat optimistic. Nevertheless, there can be no doubt that the general principle of such an aim at unification is thoroughly sound and presents an ideal which it is desirable for all nations concerned to set before themselves.

The Term "Anticyclone"

OUR English cousins are never truly happy unless they have some subject—the more academic and unpractical the better—to wrangle about in the daily press. We learn from *Symons's Meteorological Magazine* that a vehement controversy has been raging in *The Times* over the appropriateness or otherwise of the word "anticyclone," which was evolved from the fertile brain of Galton nearly half a century ago, and has since been almost universally applied by meteorologists to a system of winds blowing about a center of high barometric pressure—a "high," as it is called colloquially; the reverse of a "cyclone," or "low."

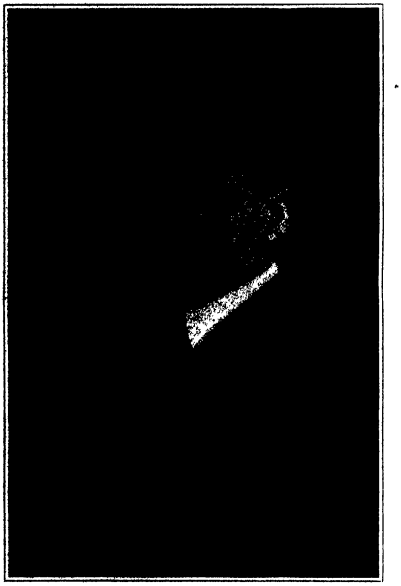
One correspondent, Mr. Pearsall Smith, suggested that an anticyclone should be called a *halcyon*, with reference to the fabled condition of the weather about the time of the winter solstice, when the halcyon was supposed to be brooding on its floating nest. Other writers, whose ideas as to the characteristics of an atmospheric high-pressure area were more or less hazy, suggested such alternatives as "calm," "air-calm," "wind-wyr," and "plenum." The first two of these are interesting as indicating that the English public is quite as much at sea as the American public concerning the proper meaning and application of the word "cyclone." The whole controversy was extremely puerile—and the word "anticyclone" is in no danger of vanishing from the meteorological vocabulary—but it is interesting as an illustration of the discussions of scientific questions by unscientific people that are rather common in English newspapers.

We may suggest that these writers might use their ingenuity to better purpose in trying to devise some acceptable substitute for the word "cyclone" in its application to a cyclonic storm. In doing so they would be following the example of certain German meteorologists who, in the last few years, have endeavored to establish a distinction between the words "*Zyklon*" and "*Zyklone*," the former meaning a violent whirling storm, and the latter a cyclonic system of winds in general.

Bion Joseph Arnold

An Engineer Who is the Right-hand Man of Public Service Commissions

By Thomas Commerford Martin



PUBLIC service commissions feed out of his hand. Public service corporations rise up and call him blessed. A court or a master in chancery is perfectly willing to accept his report on the value of a big property, as the basis for rates or new securities; and the banker is ready to accept his verdict in making large investments. There is something fundamentally fair and equitable in his mental make-up that leads to a profound confidence in his trustworthiness and ability, explaining all this. Had he been a lawyer, Arnold would have been an ornament to the United States Supreme Bench, but he would never have filed a minority opinion. He has a profound conviction as to his own insrrtincy, but believes that eleven men are more likely to be right than one. Moreover, Arnold would probably never have been satisfied with the income of a judge. Out of clean, straight engineering he makes every year as much as all the bench in Washington put together—more in one year than his father, an able lawyer, made all his life.

The Arnold family began in Rhode Island; so far as this continent is concerned, and records of the eighteenth century show a due profusion of Jeremiahs and Ichabods, which makes one look to the culture of his parent to understand how this man came to be named after a Greek bucolic poet. Anyhow, Bion J. was born at Cazenovia, Mich., August 14th, 1861, but aroused to a consciousness of things American further on westward, for his father had become a pioneer of Nebraska and a member of the territorial legislature of 1865-6. It is something to be among the founders of the great western commonwealths. Nebraska was then rather raw, and there were many struggles and privations for the newcomers on those endless dismal, but fertile stretches of black soil rolling toward the sunset from the banks of the turgid Platte. Young Arnold was never agricultural in his tastes—and, as Edison has said from first-hand observation, hoeing corn has explained the growth of many large cities. But Arnold showed his native bent by devising new types of farm machinery as a boy of six. By the time he was fifteen he had built a piston valve steam engine; when seventeen he built from an advertising cut in the *Youth's Companion* a bicycle, equal to any boneshaker of the period; and a year later he had made a complete miniature locomotive. By this time he had become a student in the Embryonic University at Lincoln, and began spending winters in college and summers as traveling expert for engine companies, or as instrument man with civil engineering parties. He graduated B.S. at Hillsdale College, Michigan, in 1884. M. S. in 1887, and M.Ph. in 1889, but was not satisfied until he had taken a post graduate course at Cornell during 1888-9. It would require some space to record his other degrees and university honors, among them being the Honorary degree of D.Sc. from Amwell Institute in 1909, but Arnold is not unlike many other engineers of distinction who are keen for the fact, but care little for the educational means by which they master knowledge. Arnold's mind is an encyclopaedia of engineering data, but those data are ever too fresh to take on the antique form of erudition.

For several years, Mr. Arnold did odd engineering jobs and lots of constructive work, settling down at last in the electrical field; building as consulting engineer in 1892-3, at the Chicago World's fair, the first electric elevated railroad in the country. He dabbled in storage batteries with engineering and financial success that startled onlookers; and then developed much of the modern electric railway practice; including the pioneer A. C. and D. C. railway between Chicago and Milwaukee in 1897-8 and the pioneer single phase line in 1904-5 at Lansing, Mich. All this involved invention, creative ability, engineering skill and personal courage of a high order—and at the end of a very short period Arnold had lifted himself to leadership in the new profession, ready for the next development.

Every student of invention and engineering knows that while the last century was taken up chiefly with the inventions that have given the world its modern facility utilities, neither the inventors nor the public have ever actually alive to the tremendous facts that now arrest attention universally—the political, economic and sociological relations of those inventions to the real welfare of the people. The awakening has been sudden and recent. We were all part of that formative regime, sharing and condoning, but we shall never go back to it, necessary and inevitable as it all was in the creation of the civilization of to-day, based so largely on inventions and arts unknown a century ago.

The chief danger now is that in the recoil of the public mind from what it once advocated and accepted so freely, vital injury may be done to the industries upon which the convenience and comfort of all depend, by reason of the restrictions placed upon the free play of individual genius and upon the opportunity offered to capital. Here comes in the vast significance of Arnold's work in what may be called his later style. He

BION JOSEPH ARNOLD

is arch adviser to the regulating and supervising bodies called Public Service Commissions, and has found a function of extraordinary usefulness in formulating the rules of the new game, in showing what is fair play, in getting a square deal for the public, in insisting upon the right of the investor to a reasonable return on the money which has helped make possible some service that crowded populations have greatly needed. Now Arnold has all the qualities of a real umpire, and might even win popularity on the baseball diamond. He knows himself, from experience, the tears and blood wrung from an inventor in reaching the goal. He has shared in the risks and discouragements of a new industry. He has helped to administer properties and knows the portentous seriousness of the problems confronted. On the other hand his temperament is judicial, his sympathies are broadly democratic, he believes that the public very often has had more coming to it than it was allowed to get under the old regime, and he is first, last, and all the time a staunch and eloquent upholder of the doctrine of the vigilant but fair regulation of utilities working under public charter and enjoying public concessions of one kind or another.

For five years Mr. Arnold was a member of the Electric Traction Commission that banished the steam locomotive from New York city and brought in the glad new era, with work running to an expenditure of $60,000,000. In 1902 he was engaged by the city of Chicago to help rehabilitate its old traction system and devise new ones. This meant valuations and studies on a gigantic scale, and since 1907, Arnold has, under direct ordinances, been chief engineer there, controlling construction operations that aggregate a cost of $65,000,000. About the same time he had charge as consulting engineer of the electrification of the Sarnia tunnel of the Grand Trunk railroad and was a member of the Commission to prepare plans for electrifying the Erie Railroad. In 1908 as consulting engineer to the Public Service Commission of the First District of New York State he made a brave essay to solve some of the mighty problems involved in the operation of the congested Interborough subways, and many of his recommendations, such as side doors for cars, speed control signals, lengthened station platforms, etc., have since been adopted resulting in great increase of capacity and earnings. With this went a lot of appraisals for the Commission of all the surface railways. In 1910 he made an intensely interesting report on the traction conditions of Pittsburgh and during the same year was appointed chief subway engineer for Chicago, preparing a report presented last February. This year he has made for the city authorities of Providence, Rhode Island, an elaborate study of the local transportation needs, and at the moment is engaged in sizing up the complicated situation at Los Angeles, Cal., where all kinds of traction services have to be tied in and coordinated for better results to traffic and commerce. These and other such jobs are large sized propositions for a big man, but Arnold measures up to them very comfortably.

While his reports are masterly in their exhaustiveness and models of completeness, Mr. Arnold's speeches and addresses when he lets himself go, are breezily western and none the less delightful. He can't help thinking clearly. As president of the American Institute of Electrical Engineers and of the Western Society of Engineers, his executive talent shone to great advantage, and as a member of many societies, clubs and civic bodies he is loyal, generous and ever companionable.

Illuminating Pistols in the German Army

DURING the recent extended manœuvers of the German army there were many night attacks, in which use was made of the newly introduced illuminating pistols. According to the new regulations these are to be employed wherever the configuration of the land makes their use preferable to that of the ordinary search light. The machinery necessary for the use of the latter device is very inconvenient, and especially in rolling and otherwise difficult country where the main maneuvers take place, it cannot be used to advantage. The illuminating pistols have not this disadvantage, as they are easily transported. Further, the searchlight is useless in valleys and deep lying plains, as their rays shoot over these and leave them apparently in still deeper shadow. For this reason, such valleys serve as excellent covers at night, against the searchlights. The illuminating pistols have done away with this advantage of shelter as the cartridges which they throw light up the deepest and darkest gulleys.

There are two different sorts of cartridges, producing respectively white and red light. The white ones serve exclusively for illuminating the country, the red ones for signaling purposes between widely separated commands or divisions even where the distance between them is several kilometers. The illuminating cartridges develop a light that makes everything within 200 meters (656 feet) visible, and lasts eight to ten seconds.

An English Plea for Aerial Navigation

THE Aerial League of the British Empire held a meeting at the Mansion House on May 24th at which it was decided to inaugurate a special coronation appeal for $1,250,000 for the establishment of a national institute and school of aeronautics.

The Opening of the Radium Institute in London

A Red Letter Day in the Annals of Medicine

IT will be remembered that the late King Edward took a keen personal interest in the advancement of cancer research, and that he was also an enthusiastic supporter of the movement for the establishing of a special radium institute in the metropolis, where the study of the application of radium for the cure of cancer and for other therapeutic uses should be carried on. The realization of this institute became possible through the generosity of Viscount Iveagh and Sir Ernest Cassel, and the official opening of the new establishment took place on August 14th.

The radium institute is equipped with all the modern appointments required for successfully carrying on what promises to be one of the most important branches of medical research. Our illustrations give only a few samples of some of the special apparatus installed. The most important asset of the institute is of course its stock of radium, amounting to 1 gramme and valued at $75,000. Among the special instruments of the institute may be mentioned a very fine chemical balance which weighs to one-thousandth of a milligramme (about one hundred-thousandth of a grain), and a very remarkable microtome, or microscope section cutter, which will make no less than 25,000 slices from one inch of material. Its extreme fineness has been graphically described by saying that it would cut a blood corpuscle into eight pieces.

The application of radium for therapeutic purposes is still in its infancy, but some of the results obtained are most encouraging, and the present juncture seems a fitting occasion to pass in brief review some of the principal methods employed and effects observed upon the healthy and diseased organism.

Radium rays have an unmistakable bactericidal action both in artificial cultures and within the organism. As may naturally be expected, the effect increases with the amount of radium and the three kinds of rays the alpha, beta, and gamma rays act in proportion to the extent to which they are absorbed, the highly penetrating gamma rays being least effective. A rather peculiar effect has been observed in the case of luminous bacteria, a small mass of radium contained in a luminous bacterial culture appeared surrounded by a small dark area, due presumably to bactericidal action. Immediately surrounding this dark area is a ring of increased brightness. The cause of this stimulating effect is unknown. According to some observers radium rays diminish the virulence of rabies toxin, but Vanyez found the rays ineffective when applied to a fresh preparation of the spinal cord.

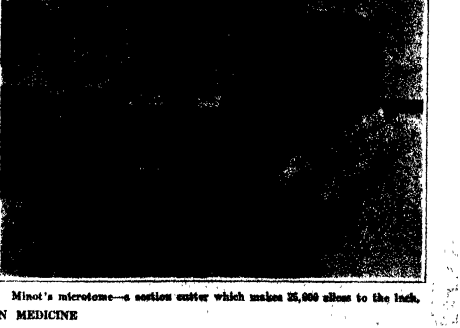
As regards the medical application of radium treatment this has hitherto extended principally to skin affections, ulcers, tumors and cancers. In the treatment of vascular tumors the radium salt is mixed with finely powdered barium sulphate, and spread with varnish in a thin layer on a metal plate. This is conveniently mounted upon a handle, and then presents the appearance shown in our illustration. The treatment, as described by A. C. Jordan in a review in *Nature* of Prof. Gaucher's book on Radiography, consists in the application of this disk to the diseased portion, the dose being regulated according to the form and extent of the tumor. Another method is to give smaller doses filtered through screens which absorb the less penetrating rays, longer exposures being in this case given. The results obtained are very satisfactory, and on the whole, better than those secured by any other means. In the treatment of scar tissue tumors very favorable results are obtained both by X-ray and by radium treatment, but radium is less liable to cause inflammatory troubles.

The activity of radium is usually expressed in terms of that of uranium. If the latter be taken as the unit, the activity of pure radium is two millions. In mixtures of radium and barium salts, the activity of the mixture is inversely proportional of the quantity of the barium salt present. In the treatment of cancerous tumors, preparations of an activity of 500,000 are used, consisting usually of four to ten milligrammes of powder containing one part of radium salt to three of barium salt. Cancers suitable for radium treatment range from those of small size to those of 20 to 30 square centimeters in area.

Deep-seated cancers are subjected to a special treatment, the rays being filtered by passing through a thickness of lead ranging from one-half to several millimeters. This permits only the highly penetrating rays to enter the tissues. Long exposures varying from 24 to 120 hours are given. It is found that the highly penetrating rays produce very little change in the healthy cells, while they have a selective action upon the cancer cells, causing their destruction. The progress of a successful case is described by Mr. J. Jordan in the review quoted as follows.

"After a short time (three to eight days) the tumor commences to diminish in size. Cicatrization then begins and is completed in two to four weeks, or longer in obstinate cases. In the case of ulcerating tumors, a certain amount of discharge occurs during all the stages. For large and deeply-extending tumors the method of 'cross-fire' is usually employed, two or more radium apparatus being applied at different points around the tumor in such a way that the ultra-penetrating rays cross in the depths of the tumor. In this way the deeper parts of a growth can be subjected to the influence of the gamma-rays far more effectively than with a single disk of radium."

In addition to the method of treatment described above, various other modes of procedure have also been proposed and practiced with varying degrees of success. Among these, it is interesting to note in particular the therapeutic use of radio-active baths, inasmuch as the supposition naturally suggests itself that some of the natural waters famous for their healthgiving qualities, owe these to the presence of radio-active substances. This subject has been much discussed, and it will suffice to remark here that probably the action in such cases takes place by inhalation of the emanation arising from the water.



A corner in the physical laboratory of the new radium institute

This balance weighs to one thousandth of a milligramme (about one hundred-thousandth of a grain).

The varnish on this disk contains $4,000 worth of radium.

Minot's microtome—a section cutter which makes 25,000 slices to the inch.

RADIUM IN MODERN MEDICINE

Atwood and His St. Louis-New York Flight

A Record Full of Promise

ONLY a few years ago, Prof. Simon Newcomb, an authority who was quoted the world over, branded the heavier-than-air flying machine as a mechanical absurdity. "I consider the demonstration that no possible combination of known substances, known forms of machines, and known forms of force, can be united in a practicable machine by which men can fly long distances through the air, as complete as it is possible for the demonstration of any physical fact to be," was one of his dicta. He followed it up with the statement: "Let us discover a substance a hundred times as strong as steel, and with that some form of force hitherto unsuspected, which will enable us to utilize this strength, or let us discover some way of reversing the law of gravitation, so that matter may be repelled from the earth instead of being attracted to it, and then, and not till then, we may have a flying machine." To drive home his conviction as far as possible, he concluded, "There is every reason to believe that mere ingenious advances with our present means and forms of force will be as vain in the future as they have been in the past."

What would Prof. Newcomb say if he were now alive? What comment would he make on the flight of a young man from St. Louis to Chicago and from Chicago to New York in a machine that did not involve the discovery of new forces or material, in a machine which was as subject to gravitation as a thing of metal and wood and canvas can be?

It may be said that Atwood's performance unquestionably proves that the flying machine has a future for swift transportation, when speed is more to be considered than cost. Atwood assures us that his expenses were $900 a day. Even if they were but a tenth of that, only a Wall Street banker who must travel from his office to Chicago swifter than a railway train can now carry him, and then because millions are perhaps at stake, can afford to pay such an exorbitant price for the transportation of his brains to the spot where they are needed. On the other hand, there is every reason to believe that so long as men like Atwood, Beaumont, Vedrines, and other present day champions of the air, race for purses that hold thousands of dollars, no attention will be paid to reduction of operating costs. When the public has wearied of aviation meets (and there is evidence that in Europe at least the cross country flight has completely displaced performances in an inclosure for the benefit of thousands in the grandstand and on the field), when newspapers have extracted all the notoriety they can by offering huge sums for successful flights between cities remote from one another, the engineer will step in and provide us with machines and engines that will transport us through the air at a cost no greater than that of a present-day automobile tour. So long as $900 a day is the cost of a flight from Chicago to New York, so long will the aeroplane be the exclusive property of aerial performers with itching palms.

In last week's SCIENTIFIC AMERICAN, we commented editorially with such fullness on Atwood's historic flight that we can do little more here than to call attention to its more salient features. In the first place, it must not be forgotten that Atwood started from Chicago after a 286-mile flight from St. Louis, made in one day at a speed of 46¼ miles per hour. That he should have flown day after day with but one mishap, speaks well for the aeroplane, although we suspect that inasmuch as the type of machine with which his victory is identified has been in existence for over a year, a large part of his success must be attributed to personal skill. To him belongs the distinction of having made the longest continuous flight on record, covering, as it did, 1,265 miles in a total flying time of 29 hours and 35 minutes, corresponding to an average speed of 42.76 miles an hour.

Of his experiences in this remarkable jaunt he says:

"My only trouble in all the 1,265 miles was a stalled motor. Think of the spots where I landed. At Lyons, N. Y., it was on top of a hill; at Amboy, west of Syracuse, it was in a marsh; at Fort Plain it was in a rocky meadow, upon the top of a mountain; at Castleton it was on a steep slope along the bank of the Hudson; at Glen, where I stopped to make repairs, it was on the top of a mountain 1,250 feet high. At Cold Spring, across from West Point, I had to climb the side of another mountain, and landed right plump on the top ledge with only a ten minutes' supply of fuel."

Copyright 1911 by American Press Association.

Atwood landed at Nyack in a small field from which he could not start.

Atwood accomplished his journey in 20 flights of an average of 63¼ miles each, with but a single forced descent at Nyack. A less steady hand and poorer judgment might have wrecked the machine at that particular time, for Atwood alighted on a piece of ground so small in area that it was impossible to start from it after the necessary repairs had been made to his motor. As it was, a few trees had to be removed and his machine had to be carried bodily to a position more favorable for starting. His Nyack mishap drives home the inevitable truth that the motor is the most vital part of the aeroplane. Until engines are absolutely reliable the aeroplane can hardly become the popular pleasure vehicle except when fitted with floats and flown above water courses where it can alight safely in case of accident.

Carrying Atwood's aeroplane to a more favorable starting place.

ATWOOD AND HIS ST. LOUIS-NEW YORK FLIGHT

A Competitor for the Trans-continental Flight

ONE of the recent graduates of the Wright school at Dayton, Mr. Robert G. Fowler, of Los Angeles, Cal., has entered the trans-continental race for the $50,000 prize offered by a New York newspaper.

The rules require that notice of the entry be given two weeks before the start that the journey must be made in 30 consecutive days, and that the start must take place before the 10th of October next. The flight may be made in either direction. Mr. Fowler has decided to follow the northern route of the Southern Pacific railroad, since by so doing he will not be obliged to fly over such long desert stretches and will at no time be over 50 or 75 miles from a town or village. The total distance over the desert amounts to 335 miles. It is planned to have a special train accompany him carrying three extra motors and complete machines. The most dangerous part of the trip is the 75 miles across the Sierra Nevada mountains from Colfax, Cal. to Reno, Nev., and the 57 miles across the Rockies from Laramie to Cheyenne, the elevations reached in these two places being 7,014 and 8,010 feet. The railroad runs along the mountain side many miles through snow sheds and a landing without disaster would be an impossibility throughout these stretches. Nevertheless, Mr. Fowler hopes to have as good luck as did Vedrines in flying over equally dangerous country in the Paris-Madrid race, and the route he has chosen gives him a saving in distance of 1,800 miles over the southern route, the total distance by rail being but 3,210 miles.

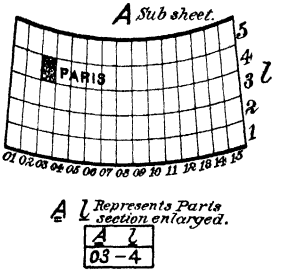
Army Aeroplanes; New Air Maps; Submarines and Aeroplanes

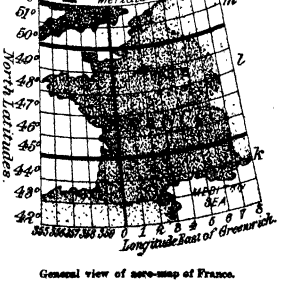


Army Aeroplanes in France

THE question of organizing an aeroplane service for the army is occupying much attention in France at present, especially in view of the coming military maneuvers which will take place in the fall M Messimy the new Minister of War, is taking active measures to make use of aeroplanes in the best possible way The maneuvers will no doubt bring out many useful points, and at the same time will give some further data for organizing an aeroplane corps for the army Steps are already being taken to do this One plan is to have a reserve aeroplane corps which does not belong to the active army, but can be called into requisition when it is needed Last year a number of pilots were called upon for an aeroplane service in this way, among others Latham, who then resumed his army position of lieutenant, and Breguet and other pilots acted in the same way This year will see a greater number of well known pilots who have made their records within a recent time, among others Vedrines, and they will take part in various operations during the maneuvers In principle, the pilots go through their annual period of 28 days which is required of all private citizens up to a certain age They will therefore not receive any money compensation, but will be rewarded by honorary distinctions or rise in grade It will be remembered that Latham, Leblanc and others already received decorations owing to their performances in the military service A point to be considered is how to recruit the aeroplanes themselves The Minister considered at first that this could be done by having one or several aeroplanes kept in hand by each constructor so that they could be called upon for use in the army in case of need, and the constructor would also furnish the pilot, receiving an annual premium of $1,000 for the aeroplane However, this plan has its drawbacks, as we find that aeroplanes are being quickly improved at present, and they would likely be out of date very soon This reason led to considering another plan, that is, a requisition of the aeroplanes from their owners such as has already been decided upon for automobiles, and as each citizen is already considered as nominally belonging to the army it is natural that he should bring his machine into service at the same time should this be needed At all events, whatever may be the plan adopted, it is certain that active measures will be taken to organize the aeroplane corps On the other hand, the Navy Department is taking steps in the same direction M Delcassé, the new Minister of the Marine, considers it best to take the pilots which are trained by the War Department in its various establishments, in order to avoid multiplying the number of training grounds The Navy Department will then proceed to purchase the aeroplanes which it needs Commandant Daveluy, a prominent naval officer, is already appointed as chief of the aeroplane service, and he formerly distinguished himself by his treatises on naval tactics The headquarters will be at the naval port of Toulon where is stationed the Mediterranean fleet, and aeroplane grounds have been already laid out near the naval docks We already mentioned that aeroplanes are to be one of the features of the next naval maneuvers and they will be used in connection with battleships and submarines Now that Aubrun found that he could sight a submarine when under water this will no doubt be made one of the features of the maneuvers, and some interesting results may therefore be expected

An International Aero Map

By Our Paris Correspondent



WITH the modern progress of aeronautics, and especially with the coming of the aeroplane, the need of specially adapted maps to serve as a guide to airmen has become strongly felt What is wanted is essentially a clear and thoroughly readable map from which the pilot can gather everything he needs, while all unnecessary and confusing detail is omitted This, however, is not enough We must have large conspicuous signals laid down on the ground and on the roofs of buildings Prof Alphonse Berget, the noted Paris scientist, the head of the department of Physical Geography at the University, gives the following account of the recent meeting of the delegates of the International Aeronautic Federation, which assembled at Brussels to discuss these questions The chair was taken by Prince Roland Bonaparte and all the leading countries were represented America sent Mr Edgar W Mix; the German representatives were Mr Hildebrandt of Cologne, and Dr Berson, the holder of the world's altitude record, Commandant Von Frankenburg and others The Austrian delegates were Commt. Th Schelmpflug and Dr. Peucker of Vienna. Belgium was represented by Col Jeanne, Mr. F Jacobs, President of the Aero Club, and others Among the French representatives were, in addition to the chairman, Prof Berget, Mr Serven and others. It was decided from the beginning to deal separately with the two questions of the map and the ground signals, equal importance being attached to each. The subject of the map was taken up first, and, thanks to the friendly feelings and unity of views which prevailed at the meeting, excellent progress was made It was decided that each country should prepare an aeronautic map upon a standard scale of 1:200,000, and further that the map of each country should be sub-divided and cut up into small sections correspond-

The Paris sub-section showing the method of designating the sectional parts.

ing to degrees of latitude and longitude The longitudes are numbered from the Greenwich meridian and the latitudes from the equator.

The French map will be drawn up along the general lines laid down by Commt Talon This method has been adopted by the Aero Club on account of its great clearness, after consultation with some of the leading experts France will be divided into 75 sub-sheets, each measuring 16 x 24 inches These sheets will be laid out according to the polyconic projection method previously adopted for the 1 100,000 map of the Department of the Interior and also for the world map To facilitate the proper assembling of the sub-sheets, they will be grouped together in a large rectangle, and each rectangle will be indicated by two letters A capital letter denotes the longitude The letter "A," for instance, includes the section lying

General view of aero-map of France.

between the meridian at Greenwich and 8 degrees east longitude. The small letter on each sheet refers to latitude, one sheet taking in five degrees. Thus, for example, the sheet "A l" takes in the greater part of France and includes a number of sub-sheets. All the sub-sheets bear the letters "A l." The main sheet is divided into seventy-five sub-sheets, each including one degree of longitude and five degrees of latitude and carrying at the bottom a number from 1 to 15 for longitude and at the side a number from 1 to 5 for latitude Thus the sub-sheet upon which the city of Paris shows is designated A l 03.4. It is these sub-sheets, measuring 16 x 24 inches, which the aeronaut will carry with him on board. Each country is to draw up its own maps with reference to this general plan, but is at liberty to choose its own method of indicating the details, except that electric power lines will be shown by lines of red crosses.

As regards the second point under discussion, namely, the ground signals, it was decided that the matter could not be properly dealt with until more experience had been gained with different kinds of signals.

Submarines and Aeroplanes

SOME very interesting experiments have just been carried out in Cherbourg, to test the capabilities of an aeroplane in detecting and locating submarine craft. The aviator who flew the machine in these tests was Aubrun, the well-known champion, who volunteered to give his services, saying that he was convinced that he could sight a submarine even when submerged at some depth from the water. The machine he used was a Deperdussin. A series of experiments was organized in which two torpedo boats and two submarines took part, as well as a steam tug designed to take the aeroplane. All the trials took place on one day, with a light wind and calm sea, and comprised two different sets of experiments In the first set, the aviator was told the approximate location of the submarines. Aubrun had no difficulty whatever in locating the first submarine, which was partly out of the water On the approach of the aeroplane it plunged and disappeared. The aviator then went in search of the second submarine and located it under water at a distance of about two miles from the first During these trials, which took place about three miles out at sea, Aubrun rose first to 600 feet and then flew at a thousand to twelve hundred feet The second trial was more difficult, but lead to complete success. In this case no indication whatever was given as to the location of the submarines, which were submerged under water. Aubrun made a fresh start from the ground and then rose to a height of about one thousand feet, sailing in large circles of 1,500 to 1,800 feet diameter over the sea. The sun was very low by this time, making it harder to view the sea bottom Before long Aubrun discovered the light reflected from a periscope, and after that it was a comparatively easy matter to locate the submarine, which appeared as a black mass moving at about 20 feet depth Auburn then returned to the ground after having been up about 20 minutes. It appears to be now beyond question that an aeroplane flying as high as 3,000 feet from the earth can detect a submarine, while on the other hand the periscope of a submarine will not give a recognizable image of a flying machine at more than 1,500 feet However, it is not altogether an easy matter to locate a submarine when the aeroplane is flying high, and the pilot must be specially trained for this work. In view of the very favorable results obtained so far it is intended to continue the trials which have been begun. For the purpose of locating submarines and torpedo boats probably a rather slow aeroplane flying at about 50 miles an hour is quite sufficient. On the other hand for scouting purposes a very rapid flyer is needed. What is particularly wanted at the present juncture is a set of maneuvers in searching for submarines lying at a depth of 60 to 100 feet under water, the aeroplane flying at different heights, and under conditions both of still water and rough seas. Floating mines also are to be searched for, and combined maneuvers, in which battleships, torpedoes, submarines and aeroplanes take part should form part of the programme. When the aviator has discovered a submarine, he discloses its location to a torpedo boat by dropping a buoy into the water.

The Population of London

ACCORDING to the latest census returns for the administrative county of London, the total population for Greater London is 7,283,982. The area of the administrative county of London is 116.3 square miles, The area of Greater London, which includes all parishes within 11 miles of Charing Cross, is 693 square miles. In 1910, the five boroughs of New York boasted of 4,776,883, although the population is now estimated at more than five million.

Wolf's and Brook's Comets

To the Editor of the SCIENTIFIC AMERICAN:

The following observations of Wolf's and Brooks's comets, respectively 1911 c and c, were made on the evening of August 20th, 1911, with the aid of the 40-inch refractor of this observatory.

Wolf's comet first observed; very apparent in the 40-inch, and in a rich field. Small Slight indication of a nuclear condensation. Near a small star.

Brooks's comet was observed, first with the 4-inch finder of the great telescope The nuclear condensation was a little more apparent than on previous evenings, but the comet was generally about the same. Secondly, with the telescope: The nucleus and matter extending in all directions from it were all that were visible at one time, on account of the size of the field of view; the former, however, presented a fairly large disk and was nebulous in appearance. The light of the nucleus was practically white. There were several comparatively bright stars in the same field, which were actually visible through the head of the comet, apparently undergoing no loss in brilliancy whatsoever. The field itself was very luminous, and in some parts the nebulosity was more apparent than in others, which fact indicated the presence of a tail extending out into space, beyond the head of the comet. FREDERICK C. LEONARD.

Yerkes Observatory, Williams Bay, Wis.

A Merchant Marine Suggestion

To the Editor of the SCIENTIFIC AMERICAN:

I wish to express my appreciation of your Merchant Marine number. I have read each of the five articles twice and find them great educators. But I note with sadness that your lay readers, the common people of the United States, upon whom rests the duty of deciding this whole matter, are not taking advantage of your invitation to discuss this problem as it should be discussed.

To them I wish to say, The trouble lies with *you* Your Congressman is afraid of your vote. Therefore he balks and actually delays the working out of the destiny of the greatest nation on earth It is up to *you*, you and Bill and John, to get busy and study this problem and make your wishes known And it is a glorious problem Try it!

To me the five Merchant Marine articles mentioned have been a means of evolution in my own ideas, and in view of the great importance of this problem I am offering my third letter on the subject, hoping that you may thus be led to see how easy it is to get into print in a really worthy periodical and on a gloriously patriotic subject, *and to try it for yourself.*

After careful consideration I believe that the following plan would the most effectually accomplish every desired result and meet every worthy objection

In order to get our just share of our commerce with each foreign nation, viz., one-half of it, without the payment of a single dollar in subsidies or the remission of a single dollar in duties, let us negotiate treaties with other nations for an equitable division of the carrying trade between each foreign country and our own, to the exclusion of vessels of all other foreign nations.

Thus, taking Brazil as an example, let American vessels loaded at home for Brazilian ports secure Certificates expressed in figures based upon the amount of cargo carried multiplied by the number of miles to be traveled The same vessel, if after unloading in a Brazilian port should reload with a Brazilian cargo for an American port, would receive similar Certificates from the Brazilian authorities. Both of these Certificates would then be exchanged for Receipts, the Brazilian goverament holding the Certificates and the American ship the Receipts. These papers might be entitled American-Brazilian Merchant Marine Certificates and Receipts. In exactly similar manner Brazilian vessels plying between Brazil and the United States would receive Brazilian-American Certificates which would be exchanged with the American authorities for Receipts.

The American vessel, upon its arrival home, would exchange its American-Brazilian Receipts for Brazilian-American Certificates, the latter having been obtained by our goverament as evidence of traffic carried on by Brazilian vessels in exactly the same manner as the Brazilian government obtained American-Brazilian Certificates. The exportation of the Receipts received by our government would conclude this part of the process.

On the next and succeeding trips the American vessel would go through exactly the same process except that it would be required to surrender to the Brazilian government Brazilian-American Certificates in amount corresponding to the amount of traffic in which it would be engaging on that trip Of course, Brazilian vessels would be accorded exactly similar treatment in American ports

Prohibitive duties, then, upon vessels of any other nation than the United States or Brazil and on vessels not presenting the Certificates would keep out all interference and leave the carrying trade between the United States and Brazil to be exactly divided between the vessels of the two nations. For no American vessel could profitably engage in the trade unless some Brazilian vessel had engaged in an equal amount of the carrying trade and thus produced the necessary Brazilian-American Certificates. Likewise, Brazilian vessels would depend for their profit upon the existence of American-Brazilian certificates obtainable in their home ports for use in our ports on the succeeding trip.

Similar treaties could be made with as many nations as might care to enter into them, and it would certainly not be difficult to find or create sufficient inducements to the ratifying of such treaties by any nations with which we might wish to carry on trade To me this plan seems so simple and effective and so free from all possible objections as to be worthy of a trial At any rate I hope you and Bill and John will get to work and see if you can't devise a better plan.

Hettinger, N D. N. J. NOBLE

Rainfall and Parasites

To the Editor of the SCIENTIFIC AMERICAN:

On page 391, issue of June 24th, you publish an article, "Rainfall and Parasites."

I am a veterinarian, with a penchant to investigation of subjects relating to my branches. These parasites require humidity, often ground covered with water, so go through the different stages of their complicated life-cycle, is well known and understood It is unfortunate that careful statistics are not kept in this country regarding the increased loss from this source, and we must refer to European statistics to study this problem.

Some years ago Dr. Hutchison, meat inspector at Portland, Oregon, by careful observation found out that cattle and sheep from overflow districts where carp were numerous, were free from liver flukes (*Distornum hepaticum* or *Fasciola hepatica*) The carp is a good scavenger, and destroyed the flukes during their water stage or destroyed the water snails that were the hosts, during a certain period of the *Cercariae.*

In the nineties I was in practice on the coast of Oregon, in Coos County There we suffered losses from *Distornum hepaticum*, especially after wet seasons, when the bottom lands had been under water and were used as pasture soon afterward Lungworms also killed many sheep and calves The life-cycle of *Filaria pulmonalis* is not known

After many experiments—attempts to cure the affected animals—it occurred to me that to prevent would be more rational Clean the pastures How?

Ducks, geese. A flock of ducks and geese will go over a good deal of ground, and destroy all forms of animal life. No doubt large tracts could not be "cleaned out" in this manner, but I remember two ranches on which, after two years of systematic running of ducks, the calves remained healthy, and the sheep were free from lungworms This latter fact was notoworthy, because the life-cycle of this parasite has not been worked out.

Some years ago, when at the veterinary department of the University of Pennsylvania, I mentioned these facts to Prof. C F Marshall, and he fully indorsed my statements, although he had never had opportunity to put the idea to actual test

The keeping of water fowl, especially ducks, is indicated in game reserves. Ravages of *Distornum hepaticum* among elk, moose, deer, are common, and the ponds are infested before we know the cause and the losses appear. But if some quarters are provided for ducks and swans and geese (they may be ornamental, although Indian runners are best) and their breeding favored, they will destroy many injurious forms of life that—no doubt about it—are necessary to permit a complete life-cycle of several parasites This has been worked out in the life-cycle of the flukes (water snails—*Cercariae*); observations that I made during several years led me to assume that the same means also prohibit the development of *strongylus filaria* and similar parasites (*vers pulmonalis*) in sheep and cattle and hogs.

Would you tell me from what paper of Prof. M. G. Moussu your article "Rainfall and Parasites" is a *résumé?*

At present I am on the staff of the local department of health and sanitation, and am therefore interested in rational prophylactic measures. I always read your valuable publications

The Left-hand Mold-board

To the Editor of the SCIENTIFIC AMERICAN

In your issue of June 17th a patent office examiner expresses surprise at seeing so many plows in the West with left-hand mold boards

When I was a boy—I am now sixty four years old—only the right-hand mold-board was made In the last thirty or forty years, I have not seen one

The advantage of the left-hand is that the leader walks in the last furrow made, and the off or right hand horse on the unplowed ground, so both are on solid ground

As the leader is usually the larger, this is very advantageous to the off horse With the right hand mold board the off-horse had to pull on soft plowed ground

You have probably received many better explanations before this will have reached you

I have had a great deal of interesting and valuable information in the last few years from the SCIENTIFIC AMERICAN, and am glad to reciprocate in a small way

Taylorsville, Ky E D BOURNE

Niagara Falls from a New Point of View

To the Editor of the SCIENTIFIC AMERICAN

It seems that a great deal of valuable energy is being wasted in hysteria over the supposed wanton destruction of Niagara Falls

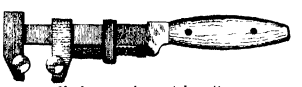
We hear great tales of woe, with heavy sob effects, ferninst the time when this beautiful cataract shall become a dribble and the wild, rugged gorge shall be but a dirty, grinding workshop where a coterie of millionaires are enabled to pile up further hoards of unearned increment, to the detriment of all "the people"

I hold that whole volumes of this kind of gush can be very easily dispensed with or turned into other channels without any injury to the body politic

It seems strange to me that in all this discussion we hear nothing whatever of the good to come to humanity from allowing this immense falls to work out its board and lodging

Here we have a force of a sum total of 5,000,000 horse-power not doing one thing but tumbling down stairs and showing off its shape (the latter being at present in bad order and going worse) But a very small part of this immense power is put to work to benefit man, while under proper management, fully two-thirds of it could be made available and the falls still left a thing of beauty and a joy forever The works now using the water seem to have their out falls on a very high level Were these at a lower level, far less water would do the same work Then look at the way the falls itself is wasting good material, there is that ugly V-shaped crotch in the "horse-shoe" where the water is now about twenty feet deep

Some aesthetic asses become very emotional over this fault, referring to it as the "great green heart" It reminds me more of a stomach, greedy and insatiable and bidding fair to soon ruin the whole show by eating back into the rock and forming a narrow sluice To this feature, more than the power houses, can be attributed the shallowness of water on the other parts My remedy is this let the State of New York and the Province of Ontario jointly build large sluice ways around the falls, their combined capacity great enough to accommodate all the water running over the falls By diverting the water to them, the edge of the falls can be built up of concrete and trimmed off to a uniform level, so that one-third of the water would at all times keep the falls falling If thought necessary the coping could be made of vanadium steel, so as to insure against any wearing away of the bed and spoiling it This would allow of an immense amount of energy to be available which would give employment to many people and furnish necessaries of life to thousands at cheaper prices than if made by using coal and that without smutting up the country with smoke In addition it would bring a good revenue to the State from the renting of water supply and it wouldn't be any more difficult than for the Panama Canal engineers to take care of the Chagres River or the Dutch engineers to keep out the Atlantic Ocean or for the Dublin police to keep the loyal Irish from setting Ireland free A strong husky man looks far better when engaged in honest toil making the world better for his existence, than when he is standing around a street corner showing off his shape and I say the same of a waterfall



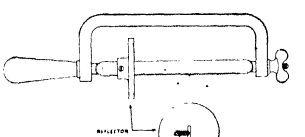
Washington, D. C. SENEX SMITH

Suggestions for the Workshop

A Simple Tube Cutter

By William Grötzinger

THE monkey wrench may be made to serve as a tube cutter by the following simple method Steel disks such as are used on the regular tube cutters are put on the jaws of the wrench These disks can be



Monkey wrench as a tube cutter.

had for a few cents from any hardware store Bore a small hole through each jaw of the wrench A stove bolt is passed through each disk and tightened to the jaws of the wrench Allow a little room for the disks to turn To cut different sizes of pipe, simply adjust the jaws, as you would to fit the wrench on a nut

Using a Reflector on a Hacksaw

By H. B. Chapman

WHEN sawing sheet metal with a hacksaw and trying to saw to a line which has been scribed on the metal, the task is found very difficult unless the light is just right Recently a man in the shop where the writer is employed made a reflector for his saw so that it would throw a good light on the

A reflector on a hacksaw.

work A round disk of brass was made as shown at *A* The disk was turned so as to have a collar at the back, a slot was cut through the center of disk so that it could be slipped over the saw A 3/16 inch set screw in the collar served to hold the disk in place while in use Some white enamel was spread over the face of disk to provide a good reflecting surface

Handy Man's Medicine Chest

By W. R. Ingraham, M.D

Remedy for Slight Burns

DOES the "Handy Man" ever burn himself? Of course One of the best, most convenient remedies he can use is a solution of picric acid in water It is very satisfying and just a little gratifying to have the excessive pain of first degree burns instantly quieted First degree burns are superficial, and the nerve endings, not being destroyed as in the deeper second and third degree burns, set up a howling remonstrance in the way of pain

Picric acid of a strength 1 to 200 (about one-third teaspoonful to one pint of water) or a saturated solution is used It is antiseptic and will prevent suppuration It is analgesic and "will make it feel good" It stains yellow, but the stain comes out in the wash Keep a small vial of the acid handy When you get a burn (if skin is not broken) sprinkle a little acid in a basin of water Saturate a strip of gauze or cloth with this and bandage in place In a very little while (or as soon as the picric acid coagulates the albuminous exudate) the pain is quieted

For Deep Burns

Use picric acid as above for deeper burns (blisters and broken skin) but be more careful Pour a little alcohol in the basin to be used Roll it about so that the alcohol wets all the inside Set it on fire and every germ in that pan dies instanter Pour water that has been boiled from the tea kettle into the pan, and add the picric acid Bandage the burn with clean aseptic gauze and saturate it with the solution Blisters should be opened and contents expressed Open them with a needle, the business end of which is sterilized by holding in the flame of a match The soot will do no harm For still deeper burns or burns of large area (third degree) much can be done by the above to alleviate suffering until physician can be had but send for him at once The attending shock is serious

For Small Cuts and Abrasions

If the Handy Man cuts his finger or knocks the skin off his knuckle he should proceed as follows I Cleanse the wound Hydrogen peroxide is becoming a favorite antiseptic and with good reason Besides being a germ killer it acts and cleanses mechanically Its effervescence dislodges and carries away dirt and any foreign matter that might infect the wound Try it on a splinter of decayed wood at which you have picked and fussed in an endeavor to extract The hydrogen peroxide "boils" it right out Therefore cleanse the cut by pouring on from a bottle a little of it, full strength (A medicine dropper is convenient) II Dust on a little aristol Aristol is an iodine compound, having the useful antiseptic properties of iodoform, but lacks the disagreeable odor and irritating properties of the latter With the exudate from the wound it forms a good artificial antiseptic scab. It may be purchased in small sifting top bottles III Apply a protective dressing A bit of absorbent cotton pasted down over the wound with collodion forms a stiff protecting shield, which stays in place May be washed over with soap and water and will not require renewal for two or three days For a contused finger nail, or cut near end of finger so liable to painful knocks it forms a stiff, comfortable thimble that is soft inside, looks better than a rag and does not interfere with work

For smaller, more superficial wounds than the above a useful dressing, better than the questionable court plaster, or even adhesive tape, is collodion, to which has been added aristol or iodoform (50 grams to the ounce) A small glass rod, the ends of which have been smoother by melting with a blowpipe in an alcohol flame, makes a convenient applicator for the collodion Pass it through the cork and leave it in the bottle permanently.

For Wounds and Painful Injuries.

In case of deep wounds the collodion dressing is not applicable and the soothing properties of a moist dressing are desired *Pour a measured quart of water into* the basin to be used Gage the quantity with your eye Throw out the water and sterilize the basin (as above) by pouring a little alcohol into the basin and rolling it about to wet all the inside Set it on fire with a match and the basin is thoroughly sterilized Pour a quart of water that has been boiled directly from the teakettle into the basin One tablet bichloride of mercury (as usually prepared) makes a 1 to 2,000 solution when added to the quart of water

Sterilize another smaller basin by the method described above and pour a part of the solution into it for later use Cleanse the wound as thoroughly as conditions permit Hydrogen peroxide of full strength or diluted with water is usually sufficient If the wound is very dirty and much lacerated, as machinists' wounds are apt to be, the following method of cleaning is perhaps better

Add to 1 quart warm water in which the wound is to be washed 2 teaspoonfuls lysol (This makes about 1 per cent solution) Lysol has an odor similar to carbolic acid, but is not so poisonous It forms a soapy solution, hence its value as a cleansing agent It numbs the parts and makes them less sensitive to pain The part should now be thoroughly irrigated with the bichloride solution in the larger basin, being sure that all the lysol solution is removed from the wound

Surgically clean gauze (sterilized, aseptic) is now bandaged over the wound and moistened with the clean bichloride solution saved in the smaller basin for this purpose Bandage lightly If the gauze dries and the wound becomes painful inside of 4 hours, remove the outer plain bandage and moisten the gauze with the solution again Use weaker bichloride of mercury solution for the next and succeeding dressings (1 to 4,000). If too strong healing granulations may be retarded.

Home Made Aseptic Gauze

Plain aseptic gauze (absorbent) may be prepared at home by the following method: For each five yards of ordinary cheese cloth use one-quarter pound common washing soda to sufficient water to cover the gauze. Boil for one-half hour and rinse in several changes of water to remove the soda This process removes the fat or oil from the fabric and makes it absorbent After it has been dried it is cut into suitable sizes—strips one yard long and four inches wide are convenient. The gauze is now sterilized and packed ready for use in the following manner: Screw top jars with caps are placed in a large bread pan, and the gauze is arranged loosely in the other end of the pan Place in the oven and bake until the gauze begins to scorch slightly. Remove pan and all to a table and while hot pack the strips into the jars Use a pair of forceps or long tweezers and a short wire for this purpose. The tips of the tweezers and wire should be made sterile by passing through an alcohol flame several times, or they may be sterilized by baking with the jars and gauze.

Seal the jars and you have a good supply of aseptic gauze ready for instant use

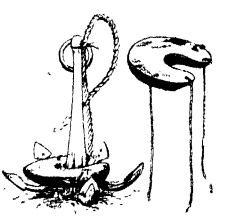
When using the gauze it is well to remove the strips with a pair of tweezers, the tips of which have been sterilized in an alcohol flame. This avoids possibility of contaminating the gauze left in the jar. A quick, convenient alcohol flame may be had by saturating a small pledget of cotton in the mouth of a bottle

Moist bichloride gauze, which is expensive to buy, yet invaluable in case of accident, is made as follows: Prepare and pack the gauze as above Then prepare a 1 to 1,000 solution of bichloride as just explained (burning out the pan with alcohol and using boiled water) Pour this solution over the gauze in the jar until it is thoroughly saturated and allow it to stand for 24 hours. Pour off the excess and seal it air-tight. If dry bichloride gauze is desired prepare the gauze as above, dry it thoroughly in the oven and repack. However, the moist gauze is to be preferred

In using this gauze observe the precaution stated above, i. e., use weaker antiseptics after 24 hours and for subsequent dressings

Moist picric acid gauze for burns may be made and kept in a jar for immediate use as follows: Prepare and pack aseptic gauze, as above Prepare a picric acid solution in the manner described (1 to 200) and pour it over the gauze Let it stand and then pour off the excess and seal it air-tight

How to Extract Broken Watch Screws



Device for removing broken screws.

SMALL screws frequently break off in clockworks, and in small machinery, and can not easily be removed A simple tool to extract the broken off screws is here shown It consists of a cramp, large enough to reach across a watch plate Provide two or three sets of 2/32-inch steel screws, with different sized hardened chisel-like points To use the tool, tighten the chisel point against the broken screw, and when you have a firm grip, turn the whole tool around, and the broken screw will invariably be drawn out

The Grapnel as a Mushroom Anchor

By Albert F. Bishop

AN ordinary grapnel can be made to give good service as an anchor by attaching to it a lead weight of U-shape, flat on the top and rounded on the bottom to fit the grapnel. This weight may be simply tied on the grapnel with cords when desired. It is not supposed to be used around a rocky or stony bottom. On a sand or soft bottom it acts like a mushroom anchor Where a small launch or boat is at anchor with a bridle it generally lies across the current or broadside to the wind This is quite important for some kinds of fishing, and it is always necessary to use heavier anchors or grapnels when in this position The lead weight is

Weighted Grapnel as a mushroom anchor.

easily cast in sand by taking a bent piece of tin and scooping out the sand to the shape desired It is not necessary to make a pattern The weight should be roughly about fifteen pounds for a ten-pound grapnel The rope is spliced in a ring at the bottom of the grapnel, brought up to the top and seized with a small cord to the ring or eye. Two turns of ordinary cord are generally enough for the seizing, which is called the trip cord.

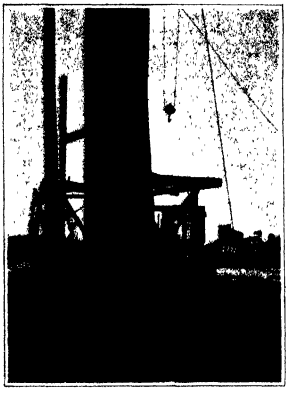
Phases of Science as Other Editors See Them

The Production of Anthracite Coal in 1910

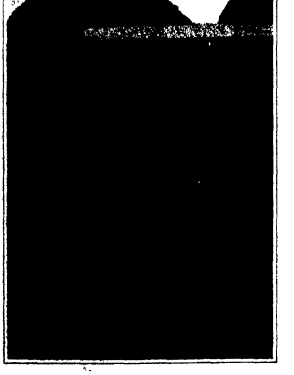
THE United States Geological Survey has issued an advance chapter from "Mineral Resources of the United States" for 1910, in which Mr. Edward W. Parker gives the following interesting statistics:

With the exception of the "boom" year, 1907, the production of anthracite in Pennsylvania in 1910 was the largest in the history of the industry. The quantity produced in 1910 was 75,433,246 long tons, an increase over 1909 of 3,048,997 long tons, or 4 per cent. The value increased from $149,181,587 in 1909 to $160,276,302, a gain of $11,094,713, or 7.4 per cent. The production in 1910 was within almost exactly 1,000,000 long tons of the maximum record for 1907, when the output amounted to 76,432,421 long tons. The value of the product in 1907 exceeded that of 1910 by $3,308,754. The average price per ton at the mines in 1910 was $2.12, against $2.06 in 1909, $2.13 in 1908, and $2.14 in 1907.



Of the total production in 1910, 65,735,024 long tons, or 87.1 per cent, were loaded at the mines for shipment to distant points, 1,804,082 tons, or 2.4 per cent, were sold to local trade and employees, and 4,894,140 tons, or 10.5 per cent, were consumed in the operation of the mines. In former years the colliery consumption was not considered as having any market value, consisting as it did of screenings, or culm, which unless so used was wasted. More recently through the invention of grates and furnaces adapted to the use of small sizes of anthracite, stimulated by the higher prices of the prepared sizes, the percentage of waste has been reduced to a minimum. "Buckwheat," "rice," "barley," and even culm are now important steam raising fuels, particularly in hotels, apartment houses, and large office buildings in the larger cities of the East, where smoke-inhibiting ordinances are in force. In fact, these small sizes are now the only grades of anthracite used to any extent for this purpose, and are the only sizes that will compete with bituminous coal for steam raising in the eastern markets. An object lesson in practical conservation is here furnished and, to the credit of the operators in the anthracite region be it said, it was put into effect a number of years before the agitation over the conservation of natural resources began. Not only are the small sizes produced in the present mining operations sold and utilized but the unsightly culm banks which blotted the landscape in the anthracite region are fast disappearing as the usable coal is being recovered from them by washeries. The prices for buckwheat at New York Harbor in 1910 ranged from $2.20 to $2.50 per long ton, rice ranged from $1.65 to $2, and barley from $1.35 to $1.50. With 65 per cent of the tidewater price representing the value at the mines, the prices for these sizes f. o. b. cars at mines were: Buckwheat, $1.43 to $1.63; rice, $1.07 to $1.30; and barley, 88 cents to 98 cents. The culm used at the mines is valued at 25 to 50 cents a ton.

Of the total production of 75,433,246 long tons in 1910, 4,184,629 tons were recovered from the old culm banks by washeries, and 81,833 tons were recovered by dredges from the bed of the Susquehanna River. The total output from the mines was 71,156,784 long tons. In 1909 the mine production was 67,945,137 long tons.



Preserving Poles

FOREST SERVICE BULLETIN 84, entitled "Preservative Treatment of Poles," contains a large amount of well-arranged information which should prove interesting, not only to many general readers, but especially to the users of telephone and telegraph poles. In the publication are summed up all the excellent results achieved by a number of experts of the Forest Service in their effort to treat poles with certain preservatives in order to increase their durability. In 55 pages of text are given the results of the co-operative experiments aiming to simplify commercial pole-treating practice by the use of the latest approved methods. The scheme of the *Bulletin* may be outlined briefly as follows: General principles of wood preservatives, results of seasoning tests; brush method of treating poles, open tank process of treating poles; results of treatment by species; design and operation of pole-treating plants; increased life afforded by preservative treatment; and financial saving. The last two chapters are of high practical interest and value to large pole using concerns whose experience warrants them in employing means for impregnating the portion of their poles most subject to decay—the butt. It is brought out that the cost of the treatment varies greatly according to the methods employed and the quantity of preservatives used, but the results are correspondingly very much better for the more thorough treatments.

Mr. O. T. Swan whose results of more recent experiments are included in this bulletin, devised the first really practical open tank method of treating the butt ends of poles. He greatly advanced the efficiency and compiled very important data which he uses to show that a great saving is possible and that plants for butt treatments may be constructed in a simple and inexpensive manner. Mr. Swan built his own design for steeping the poles and this has proved so successful that an illustration of the tank now in use is given here. The poles are treated by dipping them in a tank containing the preservative fluid by standing them in an open tank and securing an absorption of the preservative by periods of heating and cooling. Photograph of a cross section near the lower end of the poles

Experimental open tank treating plant showing successful type of pole holding frame work.

Western yellow pine cut off at the ground line showing penetration at this point by the open tank method.

is also given to show the penetration of the creosote oil.

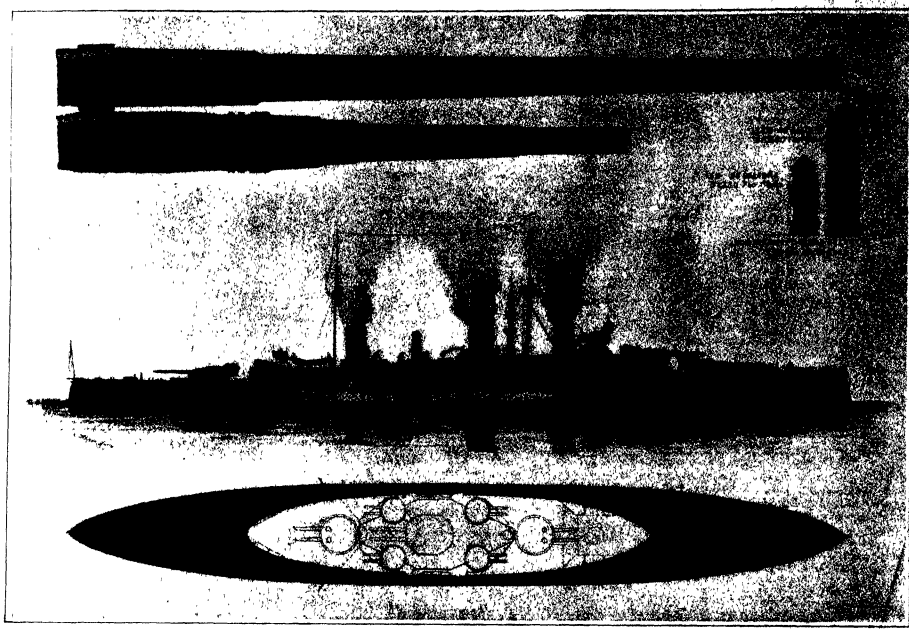
Mr. Swan is well known in the world of scientific and practical wood preservation, and the results he achieved are sure to meet a cordial welcome among creosoting concerns. His figures show painstaking thoroughness and accuracy which gives them technical and economic value.

Spruce Yarn

THE expression "mahogany overcoat" used to be employed as a sort of synonym or euphemism for coffin, but if things keep on as they have started under the impulse of inventive genius, we may soon hear of "locust shirts" and "bass wood collars" and even "long leaf pine ulsters." The Germans have long since endeavored to make themselves independent of foreign sources for the various raw materials which they require for their own home consumption, as well as to manufacture for export, and now we hear that there has been made of spruce wood a yarn that is quite spinnable. Whether this is a "yarn" or not, cannot be said but on the authority of *Der Holzhaufer*, which is many times removed from being a comic paper, and in fact revels in the most wooden of statistics for the foresters and lumber dealers of Germany, the formidably named "Aktiengesellschaft fur Garnfabrikation" of Berlin has for some time been having experiments made on the same lines as those which have resulted in the production of artificial silk and cotton; and the result seems to be gratifying, as spruce is comparatively plenty in the Fatherland, while as yet (there being no Luther Burbank on her toilet) cotton and silk are not numbered among the productions of central Europe. The new product is said to have a fine finish and much better surface than is usual with the natural fibers as yet used for spinning. The Technische Laboratorium fur Materialprufungen of the Technical School for Textile Industries in Reutlingen has shown that when leather feed rolls are used the new yarn when used as warp or chains is 124 times as strong as jute, and when used as woof or fillings, 30 times as strong. As against jute "sylvalin" has the very great advantage of being odorless, even when moist. Articles woven therefrom are naturally not exposed to the attacks of moths. If all these things are true, and the process is not too expensive there must be a good future for the new yarn, especially if (as is said) it can be worked with all the usual other fibers. The first attempts at weaving have been with wall tapestry which are most satisfactory in pattern and color, and have the great advantage of being so smooth that dust does not attach itself thereto as readily as to other stuffs used for the same purpose; also, that in brushing them down they do not get rough. So-called Japanese mats have been made of sylvalin and are hardly to be distinguished from those made of rushes. There is this great advantage on the side of the sylvalin yarn, that it may be woven in the loom, whereas by reason of the shortness of the individual pieces, rushes can be worked up only by hand. The new material has also been made up into cord of various kinds, alone and in combination with other materials, for decorative and other purposes.

One Hundred and Seventy-one Dead Horses a Day

WHILE the hot period of July in New York was more severe than usual, the deaths of work horses due to the heat during those six days is a very strong argument in favor of the electric commercial wagon.



The health department of New York city, which has the task of removing dead horses, reported that during the six working days of the hot period 171 horses died each day—a total of 1,026.

These horses represented over half a million dollars cash value, which was entirely wiped out in a single week.

In addition to this the horses not affected fatally were able to work at scarcely half their normal capacity, and fully 25 per cent of the drivers time was consumed in staving off sun stroke by frequent applications of water and frequent rests in the shade.

It is estimated that the money represented by the horses which died would pay for a sufficient number of electric vehicles to do all of the work done by the horses, and do it more efficiently and economically.

In New York city where it is estimated that there are in the neighborhood of fifty thousand draft horses not less than four per cent die annually from the effect of heat in summer and slippery pavements in winter. This million-dollar annual loss is in addition to the normal deaths, and represents a tremendous increase in the cost of horse haulage.

The 700-foot dreadnought "Lion" of 1912 is here compared on the same scale with the "Oregon" of half her length, built nearly twenty years earlier. Note the high freeboard, and the lofty elevation at which the guns are now carried.

TWENTY YEARS' GROWTH OF THE ARMORED SHIP

The New British Dreadnoughts

How the New 13.5-inch Gun is Mounted on the American Center-line Plan

THE accompanying illustrations represent the same ships of the new British warships of the 'Orion' and 'Lion' types which will commence their trials in the fall. The main points of interest in these vessels are that they are the first British ships of the dreadnought class to carry all their guns on the center line (which are of the new 13.5-inch model) and that the battleship-cruiser "Lion" is of a greater tonnage than her contemporary battleship the "Orion."

A deck plan view of the "Orion" class was given in our issue of the 27th of May together with an article on the center line disposition of guns. The points need not be recapitulated here, excepting that the further reasons given in England for the new arrangement of the main battery are (1) that the greater tonnage of the 13.5-inch prohibited so large a weight being placed on the beam (as the 12-inch were in previous British battleships) and (2) that of the *en echelon* or diagonal placing of the guns was unsatisfactory. Theoretically the *en echelon* disposition should have enabled all the guns to bear on either broadside, but in practice it was found that the designed arcs of fire had to be cut down to prevent one barbette firing into or damaging the other by blast.

The "Orion" carries ten 13.5-inch 45 caliber guns on a displacement of 22,680 tons, together with an "anti torpedo" battery of 20 4-inch quick-firers. The 13.5-inch weapons are disposed in a similar manner to the 14-inch of the "New York"; i. e., the second pair forward fire over the first, and the fourth over the fifth aft. The third pair is placed on the same level as the fifth, but the British ship cannot fire her fourth pair over so wide an arc or so far forward as the "New York" on account of the superstructure between the third and fourth positions, which does not exist in our ship. The 13.5-inch in the "Orion" (and also in the "Lion") are of a very powerful type, weighing 87 tons and firing a projectile of 1,250 pounds with a muzzle velocity of 2,821 foot-seconds, developing an energy of about 69,000 foot-tons. The penetration is 25½ inches of Krupp N. C armor at 3,000 yards, the rate of fire is the same as that of the 12-inch viz. 2 rounds in 90 seconds.

The "anti-torpedo" armament consists of 20-4-inch quick-firing guns as in previous dreadnought ships. The British admiralty apparently seem satisfied with this type of gun in spite of the employment of larger guns for this purpose abroad. They consider that the higher command of the smaller guns puts them on an equality with 5-inch or 6-inch weapons carried in a main battery. These guns, when not in use, disappear into armored shelters, a lesson evidently from the impotence of the Russian ships after the battle of Tsushima to destroy the attacking Japanese torpedo boats, owing to the wrecking of the exposed light quick-firing guns by the abnormally high-explosive shells used by the Japanese. These guns are no longer mounted on the barbette tops, but are distributed at two levels in the superstructures, and are so arranged as to bring a good proportion to bear ahead and astern, as it is from these points torpedo attack is mostly to be feared. Four submerged torpedo tubes are fitted, the torpedo rooms being inclosed in thick armor. The provision for boat stowage is of a novel type, the boats being placed between the tripod mast and the aft funnel and protected by the low blast screen seen in the illustration which conceals them. This is a remedy for the damage incurred by the boats in previous gun trials of British dreadnoughts by the concussion from the discharge of the big guns.

The dimensions of the "Orion" are 545 feet (length) by 88½ feet (beam) by 27½ feet (draught), and with 27,000 horse-power and Parsons turbines the estimated speed is 21-22 knots; the coal supply is normally 900 tons but capacity is provided for a maximum of 2,700 tons together with 1,000 tons of oil fuel. Four propellers and double rudders are used. The protection to the water line is 12 inches amidships, thinning to 2½ inches forward and aft; over this there is a belt of armor (extending to the extreme bulkheads) of 12 inches. The gun positions are understood to be 11 inches thick, the hoods being 12.8 inches thick, while stability is insured by a protected deck of 2½ inches under which are four unpierced bulkheads dividing the ship into five watertight compartments. The special internal protection against torpedo attack is of a secret nature.

The "Lion," which represents the latest development of the battleship-cruiser, is of 25,250 tons and has the enormous propulsive power of 70,000 horse-power; her designed speed is 28 knots; it is, however, confidently expected that she will attain 30 knots on her trials. For this speed a hull of fine form and great length (to accommodate the boilers and engines) is essential. The dimensions are: 700 feet (length between perpendiculars), 88½ feet (beam), 27½ feet (draught). The three enormous funnels are surrounded by steel screens to protect them from the blast of the guns; these also give protection to the boats as in the "Orion"; further accommodation for boats is made on the superstructure aft of the "wireless" pole-mast. Except for this and the low erection round the conning tower, the hull is devoid of the usual excrescences so liable to wreckage by high explosive shells. The guns are of the 13.5-inch pattern, eight being mounted, but in a different manner from the eight of the "Michigan." The second pair forward fire over the first, the third and center barbette is placed between the second and third funnels and the fourth by itself aft; all the guns fire on the broadside, four ahead and two astern. The new system of fire-control is installed in this ship (and also in the "Orion") whereby the guns can be trained in unison or independently by supplementary electric motors controlled from the range-finding position on the tripod mast. A reserve armored control-station is placed between decks; also, fire-controls are fitted to the 4-inch quick-firing guns. The searchlights are mounted on the bridge forward and on top of the blast screens.

The motive power is supplied by 42 Babcock & Wilcox boilers and Parsons turbines, the maximum fuel

(Continued on page 295.)

The Creation of "Artificial Life"

The Making of Living Matter from Non-living

By Benjamin C. Gruenberg

FROM time to time we are informed that the Riddle of the Universe has been solved by the artificial production of "life" from non-living materials. But each time we wondered how it was done, for a few days, and then find out that it wasn't done at all. The riddle is still there. The expression "artificial life" has been used in recent years for two entirely different sets of ideas.

On the one hand is the attempt to make artificial combinations of matter behave like living protoplasm—that is, to make live matter out of the non-living materials lying all about us. On the other hand is the attempt to make the eggs of various animals develop without the co-operation of the sperm—or to produce "artificial parthenogenesis," as it has been called. Both kinds of experiments are calculated to throw much light on the fundamental nature of "life;" but they differ considerably in their methods as well as in the point of view that prompts them. We shall discuss first what has been done toward the making of "artificial life" in the cruder sense.

The problem of artificial life is connected intimately with that of the *origin* of life, and also with that of the *characteristics* or distinctive properties of living matter.

From earliest times there has persisted the idea that plants or animals may arise "spontaneously" from non-living matter, notwithstanding the common experience of mankind that wherever the origin of a living thing could actually be observed, it was seen to arise from another living thing. This widespread belief in "spontaneous generation" no doubt owed its tenacity to the fact that in many cases the continuity between generations could not be directly observed. For example Eggs of eels had never been seen until within our own times; maggots were known to develop in putrifying meat, but no one had seen the flies deposit their eggs in the meat, the presence of tape-worms and other parasites within the bodies of human beings and other animals; the presence of insects within the "galls" of plants, without any apparent means of entrance—all these facts served to perpetuate the idea that life can, and regularly does, arise spontaneously. The idea that all organisms arise from pre-existing organisms is a comparatively modern one; and it was accepted on philosophical grounds long before there was any actual demonstration of the principle. From the nature of the case, however, the principle *omne vivum e vivo* cannot be proven, since it involves a negative. It is equivalent to the statement that living matter does *not* arise from non-living matter. In the seventeenth century Francisco Redi, a physician of Florence, showed that by preventing the access of insects to meat, no grubs or maggots could be formed in it, no matter how much it putrefied. In opposition to these experiments, a Scotch clergyman named Needham attempted in the middle of the following century to show by means of experiments that "wheat-eels" and other animals do arise spontaneously. He showed incidentally that tiny animalcules appeared in extracts of vegetable matter, on long standing, even after these had been boiled. But his contemporary, the Italian monk Spallanzani, showed that if the decoctions were thoroughly boiled and closed against the entrance of dust, there would be no appearance of life. Although Spallanzani's experiments were not beyond criticism, his countless tests in harmony with these, served to practically all biologists to-day—namely, that all existing plants and animals have originated from others of essentially the same kind.

But although the notion of "spontaneous generation" has been thus abandoned by all scientific thinkers in modern times, the question of the origin of life took on a new interest with the spread of evolutionary thought during the latter part of the nineteenth century. Darwin did not attempt to answer this question. He took for granted the origin of life, in some simple form, as the beginning of that evolution to higher forms which he attempted to explain with his theory of natural selection.

Apart from the theory of special creation for each species, there is only one opinion possible as to the origin of life, and that is that at some time in the past non-living material passed into a living condition—in other words, that life did originate spontaneously!" This notion of spontaneous origin of life must not be confused with the older notion of the spontaneous generation of plants and animals of all degrees of complexity.

Alfred Russell Wallace and others think it necessary to assume that the origin of life from non-living matter was brought about by the interposition of some spiritual or divine influence, of the nature of which we know nothing. Charlton Bastian and another school of biologists think that the transition of non-living matter into the living state has taken place continually from the first and is taking place now. But most biologists accept the view that living matter originated from non-living in the very remote past, and that all living things now existing are derived by a succession of generations from the primitive origins.

The Swedish physicist Arrhenius and the Englishman Lord Kelvin are strong advocates of the view that life upon this earth was developed from primitive "germs" that were brought here in the remote past "upon the wings of light" or upon some meteorites, through lifeless space. It has been pointed out a number of times that this account of the origin of life simply shifts to some other planet or system the theater of the origin, without giving us any suggestion as to the manner of the origin.

The requirements of any evolution theory are met by the assumption that life originated "spontaneously" from non-living matter at some time in the history of this planet or of the universe. But to know whether such an assumption is warranted we should know more about the characteristics of living matter, especially in its relation to non-living matter. Until comparatively recent times the processes going on in living plants and animals had been so little studied that the idea of life being dependent upon external conditions was entertained by very few men. With the development of modern physics and chemistry, and with the application of the methods as well as of the results of these sciences to the study of living things this idea rapidly spread, until it is now pretty generally accepted. Moreover the strong tendency during the past two generations to unify all knowledge, and to extend the principles of one science to the problems of all others, have stimulated the search for the physical and chemical foundations for "vital" processes.

Of all the lines of research thus developed, only three need here be discussed.

The word "protoplasm" had a varied career for about twenty years, but about fifty years ago it began to be definitely applied to "the physical basis of life" or the substance found in the cells of all plants and all animals. We know a great deal about this or what substance or rather combination of substances, but there is still a great deal more that we do not know. There have been many opinions as to the structure of this living matter that it is fibrilla that it is like a net work, that it is a mass

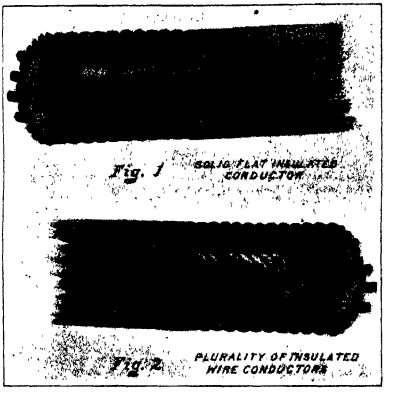
Simple Patent Law: Patent Office News: Inventions New and Interesting

The Cuntz Ocean Telephone Electric Cable

SINCE the first message was sent under the Atlantic, there has been but little change in the cable itself. The copper conductor has been enlarged and there have been improvements in manufacture, but in its essential features the latest trans-Atlantic cable is only an enlarged copy of the one by which the farsightedness and energy of Cyrus Field first joined Europe and America.



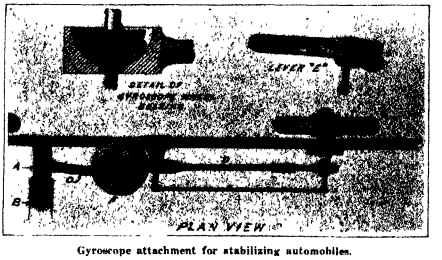
The sending and receiving apparatus at the shore ends of the cable has been improved more rapidly. By means of an artificial cable, having the same electrical properties as the real one, duplex working, or the sending of messages in both directions at the same time has been made possible, and the transmitting and receiving instruments have been made more accurate and sensitive. As the result of these changes there has been a gradual increase in the speed of transmission until now, under favorable circumstances, about forty or fifty words a minute can be sent in each direction.

But the limit of improvement appears to be reached unless the cable itself is radically changed. The cause of the slowness of submarine telegraphy as compared with that on overhead land lines is what the electricians call the "electrostatic capacity." On account of this, when an electric current is sent into the cable it must charge the whole length of the cable before its effect will be felt at the far end. A great deal of the current is used in charging the cable, and if the "makes" and "breaks" of the sending key follow too quickly upon each other, or if the direction of the current is changed too rapidly, the flow will be retarded and choked, so that no signals at all will reach the receiving end.

A rough analogy will make this action clearer. Imagine a long rubber tube with very flexible walls, through which water is to be pumped. When the water is pumped in, before any of it reaches the far end, a great deal of it will be used in distending the tube, and it will take some time for any of it to reach the distant extremity. Even when the tube is full, and the attempt is made to work the pump at the transmitting end back and forth the water pumped into the tube and drawn out of it will be used largely, if not entirely, in increasing and diminishing the pressure on the walls of the tube, and if the pump is worked fast enough, no effect whatever will be felt at the receiving end.

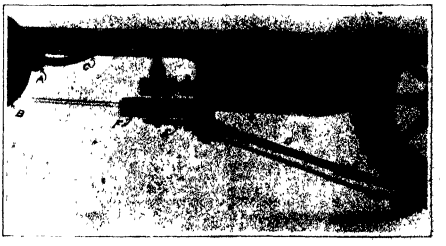
In order to get rapid action we must stiffen up the tube. If this is done, and its walls are made absolutely unyielding, any change in pressure applied to the water at one end will be almost instantaneously felt at the other end.

Now, returning to our ocean cable, if we can find some means of "stiffening" it electrically we can counteract the effect of the electrostatic capacity and enable the current to flow without retardation, and the signals to be sent clearly and quickly. A contribution toward the solution of this problem comes to us in the invention of J. H. Cuntz of Hoboken, N. J., which has recently been made public. The electrical analogy of the stiffening we put into the rubber tube is called "inductance," or "self-induction." Inductance has effects opposite to electrostatic capacity and when properly placed and proportioned can counteract it to any degree desired. As the capacity is distributed throughout the length of the cable, the best disposition of the inductance is to distribute it also throughout the cable. The problem has been to do this in a practical, commercial way, but it may now be regarded as solved. The chief sources of inductance are coils of wires, and if these coils have iron cores, their inductance is greatly increased. What has now been done is to wind the copper conductor of the cable in a long open coil about a thin central core, and thus make the entire cable a source of inductance, so overcoming the effects of the capacity and at one stroke increasing the speed of signaling ten, twenty or even fifty-fold.



A new design of submarine cable with distributed inductance to counteract capacity and render possible rapid transmission.

What has been said about telegraphy applies with even greater force to telephony. Here the minute currents caused by the vibrating diaphragm of the transmitter vary at the rate of hundreds and even thousands of alternations a second, and in an ordinary ocean cable they would be choked up and obliterated after going a few miles. In underground cables the effects of capacity are also very troublesome, and telephony has been greatly hampered on this account. But a method was devised a few years ago (by Prof. Pupin of Columbia University) which has been very helpful in underground telephony, as well as on long overhead lines. By this plan inductance coils are placed at intervals along the cable so as to approximate the effects of uniformly distributed inductance.



For long-distance submarine work, however, such coils would be impractical. They make bumps and introduce mechanical weaknesses which would cause difficulty and danger in laying a deep sea cable, and would increase the cost of maintenance and repair probably to a prohibitive degree.

The new cable, which has just been patented by Mr. Cuntz, avoids these difficulties and is conspicuous for its strong and compact mechanical design, in addition to its efficient electrical properties. As its process of manufacture becomes systematized, it will be made at a cost little, if any, in excess of that of the present cables, and it can be laid and maintained with no greater expense. Its use will vastly increase the speed of submarine telegraphy, and will have a most marked influence in lowering cable tolls. At the same time it brings us at last to a realization of the long-cherished dream of ocean telephony.

Think what it would mean to have Washington in telephone communication with Panama, and business men in New York and London within talking reach of each other.

Gyroscope attachment for stabilizing automobiles.

View showing the normal position of the trailing wheel.

A Gyroscopic Stabilizer for Automobiles

A RECENT newspaper article contains an interesting account of a test made on a slippery surface to demonstrate the effectiveness of a gyroscopic attachment for preventing automobiles from skidding. The attachment is described as being made under Rutt patents. This probably refers to an English patent, No. 12,842, of 1906, granted to Alfred Rutt of London. In this English patent the gyroscopic principle causes a pivoted trailing lever to oppose any swerving or skidding motion of the vehicle. In operation, the rotation of a friction wheel *A*, driven by the fly wheel *B*, is transmitted by a flexible shaft *C*, to a spindle on which the gyroscope wheel *F*, is fast. When the car tends to skid, the lateral displacement resulting therefrom, causes the trailing rod *D*, by the friction of its trailing wheel on the ground surface, to assume an angular position and so swing a lever *E*, which carries the gyroscope wheel *F*. This tilts the gyroscope wheel from its normal plane of rotation and produces the combative force directed laterally against the frame of the vehicle in opposition to the side slip and operates to maintain or immediately restore the equilibrium of the vehicle.

The gyroscopic principle has been suggested as a means of securing stability and persistence of direction in various forms of vehicles. It will be recalled that a small gyroscope is provided within the shell of some forms of dirigible torpedoes to aid in holding the torpedo on its course. In 1877 a patent was issued in the United States for an aerial machine which embodied gyroscopic wheels, one with a normally horizontal axis and the other with a normally vertical axis for the purpose of preserving the equilibrium of the machine and preventing its upsetting. In 1888 C. Benz of Mannheim, Baden, Germany, secured a United States patent for a self-propelling vehicle in which he supports the fly wheel on a vertical axis whereby it will revolve in a horizontal plane so that "the vehicle is not only easily controlled but also the greatest safety is attained against capsizing."

Other instances in which the gyroscopic principle is utilized in an effort to secure stability in automobiles, will be found in numerous United States patents including Nos. 564,127; 637,750; 653,364; 734,283; 859,293, and 907,907, to which the attention of those especially interested in the subject is directed.

Medical Compounds from a Patentable Standpoint

AT one time, new medicinal mixtures of substances of previously recognized medicinal virtue, were regarded as patentable. In recent years, however, this view has been considerably modified by decisions such as that of Assistant Commissioner Fisher, rendered May 29th, 1890,

in the case of Crippen, in which a medicinal mixture was held to be

"wanting in patentability because it covered nothing more than such a compound of medicinal agents as could be made by the exercise of the skill of a physician."

The doctrine of this decision has been followed by the Patent Office tribunals, including the Board of Examiners-in-Chief (whose decisions are not published), and is generally applied to medical compounds which are made up of ingredients known as medicinal of which any physician is expected to make such selection as his judgment may dictate for the treatment of any case he may have in mind.

Darlington's Personal Property on page 227 says:

"It is doubtful if a mere prescription forming the body of a so-called 'patent medicine' (more properly a proprietary remedy, since they are usually not patented) really exhibits invention; for no matter how good and efficient (many are very good) it is still a question whether (other conditions being disregarded) where the result of medical education has brought in a formula for the cure of disease there is anything beyond technical skill."

Some substances not previously used in medicine may give patentability in mixtures in which they are employed. It must not be thought, however, that this is a conclusive test of patentability as it must be considered whether the new ingredient is essential and material in its effect on the mixture, also whether the mixture is a true combination or only an aggregation, for many medicinal mixtures are not patentable, because the mixture possesses no demonstrable effect other than that which would result from the ingredients taken separately

Apart from medical compounds, processes of treatment have been held unpatentable. In the case of Brinkerhoff, decided July 5th, 1883, Mss vol. 24, pp. 349, Commissioner Marble says.

"The methods or modes of treatment of physicians of certain diseases are not patentable; they are discoveries which may in a majority of cases under certain conditions accomplish certain results, but no particular method or mode of treatment under all circumstances and in all cases will produce upon all persons the same result, and hence to grant a patent for a particular method of treatment would have a tendency to deceive the public by leading it to believe that the method thereby described would produce the desired result in all cases"

The Court in Morton v New York Eye Infirmary, Fisher, vol. 11, page 320, held.

"The application of ether to surgical purposes was an effect produced by old agents operating by old means upon old subjects The effect alone was new, and was a mere discovery, which, however novel and important, is not patentable,"

and suggested that the patent law is

"inadequate to the protection of every discovery by securing its exclusive control to the explorer to whose eye it may be first disclosed."

and

"Neither the natural functions of an animal upon which, or through which, a new force or principle may be designed to operate, nor any of the useful purposes to which it may be applied, can form any essential parts of a patentable combination with it, however they may illustrate and establish its usefulness"

As nearly as can be easily determined, about nine patents were granted during the past year for medical compounds.

Medical compounds, however, must not be confounded with chemical compounds, since definite individual chemical compounds are, if new, patentable, whether intended for medicinal use or for some other purpose

A Puncture Proof Tire

ACCORDING to Consul James E. Dunning, Havre, France, Mr. George Longuemare of Havre has patented and put into practical use an invention for preventing punctures in pneumatic tires which he calls "a puncture-proof metal band for pneumatic tires." The chief features of the invention are:

A band of canvas covered with small hexagonal metallic disks. These disks are arranged to fit closely one against another, and are riveted to this canvas so as to form a flexible armor.

The band of canvas thus prepared is placed in a sheath of rubber. In order to safeguard the tire, this sheath is placed between the air-tube and the outer cover. The air-chamber cannot be punctured, and even cuts in the outer cover are in no way harmful. Experiments have shown that there is considerably less heating of the tire, and that resilience is the same.

Different experiments are said to have been made before responsible witnesses to prove that nails, broken glass, etc., cannot cause punctures when the air-chamber is thus protected, and the results are reported to the Consul to have been entirely in favor of the invention.

For example, two one-inch nails were driven into the outer cover and the automobile, with four passengers, was driven five miles before further examination was made. Then the tire was removed and it was found that the air-chamber had not been touched by the nails and that even the armored device had not suffered, the nails having met the quite imperforable steel disks.

Notes for Inventors

Honors to Theodore Timby.—On August 10th, Senator Clapp of Minnesota introduced in the U. S. Senate a joint resolution directing the Secretary of the Navy to commission a warship to convey the remains of Theodore Ruggles Timby from Brooklyn to Washington, D. C., on October 12th, 1911, for burial The resolution recites that Timby, an American citizen, conceived the idea of and invented the revolving turret which was afterwards adopted by John Ericsson in the construction of the Monitor, and which made that vessel so effective in battle, and that his native State, New York, by a concurrent resolution, on May 2nd, 1890, regarded it as "a fitting if not an imperative duty of Congress to do ample justice in the premises and vindicate the genius that contributed so largely to rescuing the country from a grave peril." The resolution also recites that the Patriotic Association of America, the Monitor Association of Naval Veterans, and Naval Post 516 of the Grand Army of the Republic, appreciating the service rendered by Timby, are preparing, at their expense, to bury his remains in his family cemetery plot in Washington and they wish the commission of a warship be commissioned to convey the remains as a tribute of respect to his memory It appears from the resolution that while the remains of Timby remain in the receiving vault of a cemetery in the city of Brooklyn unhonored and neglected, the construction of the Monitor brought John Ericsson fame and wealth and such distinguished honor that our Government, as a tribute to his memory, sent his body to Sweden, his native country, for final interment After considerable discussion, the House Committee on Naval Affairs decided against recommending the adoption of the resolution, thus sustaining the position of Assistant Secretary of the Navy Winthrop, who thought it improper to thus give any basis for a claim on Congress for an appropriation in consideration of the services of Mr. Timby.

A New Kind of a Spinning Top.—An attractive spinning top is the subject of a patent, No. 999,839, to James R. Myers of Fairmont, W. Va., and has a disk and a tubular spindle molded integrally of glass. Translucent color circles are provided on the upper surface of the disk and a pin can be inserted in the spindle for spinning the top.

A Coating Machine.—A machine for coating articles is shown in a patent, No 999,789, as the invention of Alfred R. Hussey of Harvard, Mass. There is provided a revolving form for the article to be coated and this is revolved in front of a number of stomizing nozzles which direct the spray against the sides and at a downward inclination against the top of the article, means being provided for supplying the coating liquid and air and for controlling the air supply.

A Reinforced Railroad Tie.—William D. Forsyth of Youngstown, Ohio, has patented No. 999,771, a reinforced railroad tie, having a rail fastening device, including a flanged sleeve, embedded in the concrete to receive and retain a non-metallic resilient bushing and thus bushing is adapted to receive and retain an adjustable metallic split sleeve.

An Edison Storage Battery Patent.—Edison Storage Battery Company, West Orange, N J., is patentee No. 999,762, as assignee of Thomas A Edison, of a storage battery and process of treating same in which the process consists in soaking the pockets carrying the active material in a solution of bismuth tri-chlorid in acetone The active material for the negative electrode of the battery comprises electrolytically active finely divided iron, and bismuth intimately associated with the active particles

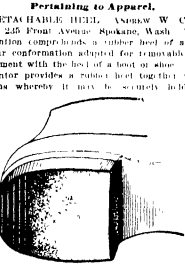
Listening to the "Innards" of an Automobile.—Leonard B Gaylor of Stamford, Conn., has taken out a patent, No 999,496, for a device for locating the defectively operating parts in automobile motors and other mechanism and including a hollow ear piece and diaphragm casing, open at both sides, and a rigid test rod, the unconnected end of which is made of non-combustible material Gaylor seems to have invented an improved stethoscope for automobile use

A Concrete Railway Tie.—A railway tie with a concrete body and a core-reinforce in the form of an I-beam, enveloped in the body, is shown in a patent, No 999,449, to Joseph J Harrell of Chicago

Matches from Grass and Straw.—A London paper tells of a process, said to be in the experimental stage, for manufacturing a wood substitute from dried grass or straw, which is primarily intended for use in the manufacture of matches At the conclusion of the process, which is described as including crushing and stripping the straw and compressing a flat layer between sheets of paper and subsequently molding the splints, the latter are cut to length and dipped in the match composition When the scarcity of wood renders desirable the use of a substitute in match making in this country, a fruitful field will be opened to inventors

A Novel Concrete Pile.—Two patents, Nos 999,440 and 999,441, have been issued to Richard J Beall, Jr., of Washington, D C The applications for these patents were filed in April, 1904 The patents relate to concrete piling, in which a tube, whose bore is unobstructed, has an enlarged separable point closing its lower end and when the point and tube are driven into the ground to the extent desired, the tube is withdrawn without the point, the opening above the point being filled with concrete deposited in the tube during the withdrawal of said tube

Preparation of Milk.—The preparation of milk for delivery to customers forms the subject of a patent, No 1,000,409, to Frederick W Howe of Framingham, Mass His method consists in filling the milk bottle with milk freshly drawn from the cow and withdrawing the gases and animal heat from the milk by a vacuum producing device a permanent seal being applied to the bottle without the access of atmospheric air



A New Conduit Creeper.—A creeper, which can be moved from one end of a conduit through or toward the other end of the conduit, has been patented, No 1,000,825, to Henry G Lehman of Windber, Pa It includes a frame, having means for releasably engaging the conduit, and a carrier movable relatively to the frame and also having conduit engaging means, and jerk ropes are connected, one to the carriage and the other to the frame so that the carriage and frame can be advanced alternately, step by step, to feed the creeper through the conduit.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

DETACHABLE HEEL, Andrew W Carlson, 235 Front Avenue Spokane, Wash This invention comprehends a rubber heel of a peculiar conformation adapted for removable engagement with the heel of a boot or shoe The inventor provides a rubber heel together with means whereby it may be securely held in

DETACHABLE HEEL

position on the heel, a rubber heel being provided with an exceptionally engaging means whereby it may be positioned on the heel A perspective view is given in the engraving showing the heel in position with the fastening means The device is adaptable for use in cases where one may desire the rubber heel at some times during the day and its removal at another time The fastening means comprises a heel number having inwardly extending portions and it is formed of resilient metal

Of Interest to Farmers.

TRAP NEST F H Sessions, Denmark Maine This invention provides means whereby it may be determined which hen has laid any particular egg and also to avoid any annoyance of the hen while on the nest It can be readily cleaned, to which end its several parts are detachable or separable and which will effectually trap the hen without preventing the fowl from leaving the nest when desired

ENDLESS CUTTING APPARATUS FOR MOWERS. J H Rogan Columbus Mont The accompanying illustration pictures a cutting bar having a sickle bar moving continuously in one direction thus dispensing with the wear and tear and heavy draft of the usual

ENDLESS CUTTING APPARATUS FOR MOWERS.

reciprocating bar, and lessening the cost of operation and maintenance of the mowing machine The cutter bar may be attached to any form of machine mower, and will run with great smoothness By removing an upper plate, the cutting mechanism may be removed for any purpose, and the bar as a whole may be made of any suitable length It is easily and cheaply operated and the mechanism is intended for a construction of long life

Of General Interest.

ELEVATED CARRIER. P J Dacuka Honolulu, Hawaii The object here is to provide a carrier for the transportation of field products merchandise and the like arranged to slidingly support the parts which forming the track for the lower supporting trolley or carriage to run on so that the cable is not liable to leave the support especially along abrupt changes in the grade of the track or cable

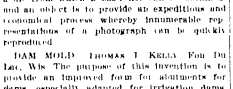
INSULATING COMPOSITION W Rumel Salt Lake City Utah This composition is an improved insulation for boilers steam pipes refrigerator pipes and appliances, and such other apparatus to which a non-conductor of heat is to be applied The material is cheap thick cheaper than asbestos and offers a more effective barrier to radiation between two mediums of different temperatures although it is not claimed that the composition will withstand the ravages of fire

RAILWAY CATTLE GUARD CAUSEWAY S J Billington and J A Stephenson Ellis ton, Mont This invention provides a novel structure arranged to form a shifting slipping platform to prevent the passage of cattle through the openings in fences provided for railway cuts provides means for preventing the entanglement of the parts of the platform with the structure of a moving car and provides attaching devices for the rigid structure which are simple and durable

ADVERTISING DEVICE H A Van Syckel New York N Y This invention has reference more particularly to a device in which a movable series of advertisements notices, or other announcements publications or the like, are successively presented to view, and which has means for advancing the series of advertisements and for reversing the direction of movement of the same automatically, so that the series can be repeated

HOD STAND S H Adams Phoenix Ariz The aim of the inventor is to provide a construction of folding hod stand which can be

adjusted to any size of mortar or brick hod and hold such hod when applied to the stand at any desired angle. The stand in practice may be made of wrought iron of suitable size and dimensions to give the necessary strength for supporting the hod.

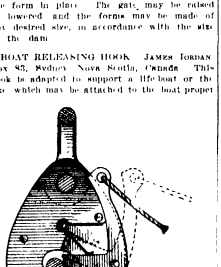


NON-REFILLABLE BOTTLE.—S. R. KELL, New York, N. Y. This non-refillable bottle is arranged to govern the discharge of the liquid from the bottle and to prevent unauthorized persons from refilling the bottle with spurious goods. For this purpose use is made of a valve in the neck and a plunger operating in the neck below the valve thereof to allow of forcing the liquid through the valve on actuating the plunger.

SHEET HOLDER.—J. PODOLAKER, New York, N. Y. The invention pertains to a holder adapted to support and secure a plurality of sheets in an assembled and readily accessible position, these sheets being of any suitable character such as newspapers, blue-prints or the like. An object is to provide a plurality of clamping faces between which any desired sheets may be secured and held in position by a lock.

CORN SUPPORT.—A. L. HAMMOND, North Platte, Neb. This invention relates generally to implements used by mule-takers and more particularly to a device adapted to bring the jaws into proper position with each other when laying out a body. The aim is to provide a chin rest especially adapted to hold the jaws in such position that in the event of the body being laid out having false teeth the said teeth will be prevented from slipping.

PROCESS FOR MAKING PRINTING BLOCKS AND STAMPS.—ALFRED J. JARMAN, New York, N. Y. This invention relates to the process of making printing blocks and stamps from photographic negatives by the use of a specially prepared printing paper, a mold and a die from which a bas-relief can be obtained and an object is to provide an expeditious and economical process whereby innumerable representations of a photograph can be quickly reproduced.

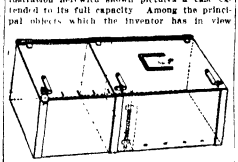


DAM MOLD.—THOMAS J. KELLY, Fon Du Lac, Wis. The purpose of this invention is to provide an improved form for abutments for dams, especially adapted for fish dams, and wherein the abutment is so arranged that the gate while supported in an efficient manner may yet be lifted to release the water or lowered to hold the same. The dam to be built is preferably composed of two abutments

DAM MOLD.

of concrete one on each side of the stream and connected by the dam proper. A plan view of the improvement is given in the illustration and it shows an abutment completed and the form removed and the other abutment with the form in place. The gate may be raised or lowered and the forms may be made of any desired size, in accordance with the size of the dam.

BOAT RELEASING HOOK.—JAMES JORDAN, Box 85, Sydney, Nova Scotia, Canada. This hook is adapted to support a life boat or the like which may be attached to the boat proper



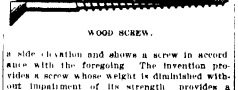
BOAT RELEASING HOOK.

or to tackle and which is adapted to automatically release the boat from the supporting members by the simple movement of a catch. The invention provides a releasing hook in which the weight is supported on a stationary member, and in which the link engaging the hook is held in position on the supporting member by a latch, so that little or none of the pull on the link will be exerted on the latch so that the latter will be readily operated and certain which the parts are so arranged that any tendency of the link to slip out of position will draw the latch down so as to more firmly hold it in place. The engraving shows a fragmentary view of a boat with the device attached thereto.

HORSESHOE.—N. SAWCHUK, New York, N. Y. This invention has reference to horseshoes, the more particular purpose being to provide a shoe to be connected with the horse's foot without the aid of nails or other similar fastenings, and also without the necessity for any part binding tightly upon any sensitive portion of the hoof.

FOUNTAIN BRUSH.—W. L. PERLEE, Greenville, Texas. In this improvement use is made of an apertured brush body provided with lateral an apertured casing mounted to slide on the body, a valve adapted to normally close the apertures in the casing, a spring in the casing and adapted to engage the valve with the said casing, and a second casing adapted to constitute a cover for the brush body and a reservoir for a liquid or a holder for the fountain brush liquescent substance.

COLLAPSIBLE PACKING CASE OR TRUNK.—E. S. SHEPHERD, 1462 E. 94th Street, Canarsie, Brooklyn, N. Y. The illustration herewith shown pictures a case extended to its full capacity. Among the principal objects which the inventor has in view



COLLAPSIBLE PACKING CASE OR TRUNK.

are: To provide a carton or case or trunk for transshipment of merchandise or other goods which may be adjusted to size to meet the requirements of shipments and to economize the cost of handling by reducing the bulk dimensions of the returned or empty case, to provide a structure for boxes or cases of the ordinary character mentioned which is more durable than the form at present provided, and to provide means for locking the case which automatically locks or fixes the size of same.

Hardware and Tools.

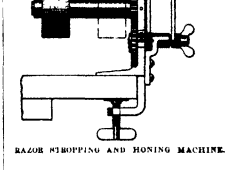
WOOD SCREW.—R. DEWITT BURDICK, Lincklaen Center, N. Y. Inventor: I. L. Messenger. A wood screw constructed in accordance with the present invention differs from the ordinary screw in that the opposite sides thereof and longitudinally disposed thereon, channels are formed. The engraving illustrates

WOOD SCREW.

a side elevation and shows a screw in accordance with the foregoing. The invention provides a screw whose weight is diminished without impairment of its strength, provides a screw the threads whereof are sectioned to form a plurality of cutting edges for the threads and a relief passage in the barrel of the screw, and provides a screw the head whereof permits the use of a counter-sinking driver.

STROPPING MACHINE.—J. W. HAWKINS, Passaic, N. J. In this device a drum is provided having a blade supporting roller on each side of the drum so arranged that when the rollers are engaged with a plane surface, the portion of the drum between the rollers will also engage and roll on the same surface, thus rotating the drum, and causing the rollers to hold the blades against the drum in stropping position.

RIVET MAKING DEVICE FOR CHAINS.—FRANK B. WIDMAKER, 2312 Broadway, New York, N. Y. This device may be readily carried in the tool bag of a motor-cycle or automobile, for use in repairing the drive chain of



RIVET MAKING DEVICE FOR CHAINS.

the machine. It includes a punch and a hammer for driving the rivet out of the punch. The head of the hammer is so constructed to receive and hold the chain, while the punch serves as a handle to turn a screw on the head of the hammer, to loosen the rivet preparatory to driving out the last. The device is shown in the engraving with the parts in position for starting a rivet from a chain, for which it is generally useful, but it is especially designed for use in the repairing of the drive chains of automobiles and motor vehicles.

HARNESS BUCKLE.—T. MCNARY, Jackson, Tenn. This inventor provides a buckle in which the tongue passes through the perforation in the article to be buckled instead of passing through it in a slanting direction, the ordinary form serving to wear the strap on one edge and to eventually cut it. Strain on the tongue is relieved by plates which serve to protect the tongue and also to clasp the straps over the side, this assisting in holding the strap in place.

RAZOR BLADE STROPPER.—I. KLEIN, New York, N. Y. The invention refers to a device for use in holding safety razor blades of various types during the operation of sharpening. The sharpener comprises a holder consisting of a plurality of leaves hinged together and having projections and recesses for securing the different types of safety razor blades so that they can be readily stropped or sharpened in any suitable manner.

RAZOR STROPPING AND HONING MACHINE.—CHRISTIAN ALTER, 500 E. 83rd Street, Manhattan, New York, N. Y. The object of the inventor is to provide a stropping and honing machine (a plan view of which is shown in the engraving) arranged to permit stropping or honing of ordinary razors

RAZOR STROPPING AND HONING MACHINE.

or the blades of safety razors in a very simple manner, it being only necessary to exchange a stropping wheel for a honing wheel when using the machine for stropping or honing purposes. For this result use is made of a wheel having a peripheral stropping or honing face and mounted to turn in either direction and to travel in the direction of its axis and a holder for the blade mounted to rock to present either side of cutting edge of the blade to the peripheral face of the wheel, according to the direction to which the wheel is turned.

PIPE WRENCH.—P. J. MCGUIRE, New York, N. Y. This pipe wrench embodies a flexible gripping member, ordinarily in the form of a chain at the end of a lever, and has in view such a wrench in which substantially no travel of the lever is required to draw the gripping member tight about the pipe or fitting after the member is applied, and which effectively grips the pipe or fitting for substantially the full circumference.

Heating and Lighting.

DRIER.—P. JACKSON, Macon, Ga. This invention is an improvement in driers embodying a rotary tubular conveyer, and has in view such an appliance in which the hot gases from a furnace are discharged through the conveyer in a direction opposite to the travel of the materials to be dried, the furnace and conveyer being arranged end to end, with the discharge end of the conveyer constructed to shower the materials through the hot gases and flame of the furnace.

LAMP BOX.—W. R. BOWLES, Hopkinsville, Ky. In this case the object of the improvement is to provide a simple and inexpensive box especially adapted for photographic work and wherein a negative, picture or other object to be operated upon may be illuminated to the best advantage and with the proper character of light.

Household Utilities.

FURNITURE FOOT SOCKET.—O. TRINDER, East Douglass, Mass. This invention provides a rest in the form of an adjustable cup head for the legs of a radiator or other article of furniture, the vertical dimension whereof may be varied, provides in a device of this character means for partially locking the device in set position, and provides a device which is simple, economical and durable in construction.

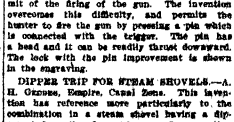
Machines and Mechanical Devices.

PROPELLER FOR AEROPLANES.—T. S. HARRIS, Waverly, Ill. Among the principal objects which the present invention has in view are: to provide a propeller wherein the rotation of the same is automatically governed; to provide means for manually controlling the adjustment of the governor; and to provide a simplified, efficient and durable construction for a propeller.

LOADED TRUCK COUNTING APPARATUS.—E. MCGARRY, Walla Walla, Wash. This invention provides a platform and compensator operatively connected therewith for ascertaining the succession of loaded trucks or conveyances passed over the said platform; provides a platform to operate under conditions of load only; and provides a platform and compensator connected therewith constructed and arranged in a manner economical, durable and efficient.

LIQUID PISTON VACUUM PUMP.—M. A. MOULIN, 303 Rue du Faubourg St. Antoine, Paris, France. This invention is characterized by the employment of a frictionless and loosely fitting piston whose tightness to gas is insured by a liquid without appreciable vapor pressure, which need not be lubricating, which by reason of its viscosity leaks through slowly in comparison to the speed of the system; the liquid escaped being afterward utilized to drive out gas filling the space where it is not wanted. A complete vacuum may be rapidly attained with little liquid, an important point when mercury is used.

AERIAL VESSEL.—S. A. NOBLES, Albany, N. Y. The object here is to provide an aerial vessel or aerosel, of the kind known as heavier-than-air flying machines, the vessel being provided with large sustaining surfaces capable of being moved to support the vessel, to elevate or lower the same, to propel and steer and to automatically restore the equilibrium of the vessel when struck by contrary air currents.



COPY HOLDER.—B. F. PERRY, H. S. MCDANIEL and N. W. THOMPSON, Portland, Ore. An object of this improvement is to provide a copy holder in which the copy may be fed forwardly by the mere act of operating the typewriter machine. It relates more specifically to novel means for effecting the feed of the copy in which the feed mechanism may be operated by the movement of the typewriter itself, or manually if desired.

VALVE.—S. STUCKY, Oxford, Ala. In this instance the purpose of the invention is the provision of a mechanism for use with ordinary form of outlet valve casing for closing the passage of the valve casing, when the valve is removed for any purpose, and wherein the said mechanism is normally held in inoperative position by the valve.

STOCKING FOLDER.—A. L. PATTERSON, Albemarle, N. C. The improvement is a means provided for folding stocking tops preliminary to sewing the same to form the hem at the top of the stocking and the invention includes means by the use of which the stocking may be folded accurately and to any part thereof as desired, ready for sewing on a hemming machine. The stocking tops may be folded to any desired width of hem which may be varied according to the length or extent of movement of the blade.

RIVETING MACHINE.—H. LLOYD, Lexington, Ky. In this patent the object of the invention is to provide a very powerful hand operated device which will be light, compact and handy, easy to operate, and consisting of but few parts. The device is a die having an anvil co-operating therewith provided with means for holding a rivet in position to cooperate with the die to perforate a sheet of metal, the hammer and anvil being further provided with means for heading the rivet.

FIRING MECHANISM FOR GUNS.—ETHAN ALGER, 214 Arizona Avenue, Lorain, Ohio. Mr. Alger's invention has reference to firing mechanism for guns, and it has for its object

FIRING MECHANISM FOR GUNS.

the provision of means for firing a gun which may be readily actuated with heavy guns or warm mittens. In hunting in winter weather it is very difficult to pull the trigger when gloves or mittens are worn, and without gloves or mittens the fingers become too numb to permit of the firing of the gun. The invention overcomes this difficulty, and permits the hunter to fire the gun by pressing a pin which is connected with the trigger. The pin has a head and it can be readily thrust downward. The lock with the pin improvement is shown in the engraving.

DIPPER TRIP FOR STEAM SHOVELS.—A. H. GEROME, Empire, Canal Zone. This invention has reference more particularly to the combination in a steam shovel having a dipper, a door, therefor, and means for operating the dipper, of a latch for the door, a cylinder to receive a rigid under pressure, a piston in the cylinder, a pivoted lever operatively connected with the piston, an operative connection between the lever and the latch whereby the piston can be actuated to release the door, and a dead stop to limit its movement.

CONDENSED HANDLE AND PULLEY FOR CREAM SEPARATORS.—P. A. FREEMAN, Slot Springs, S. D. It is important that centrifugal cream-separators shall be run at a uniform speed, and, since the pin customarily used

machine ordinarily employed for driving them often, such as varying speeds, or, in coming machines, have a "jerky" motion, spring attachments have been devised for connecting the band-wheel or pulley with the shaft of the separator. Mr. Shoberg's invention is an improvement in this line.

ROTARY PUMP.—A. P. SMITH, Winnebago, Nev. This improvement provides a pump wherein the lifting power is supplied by weighted members which may be varied to harmonize with the conditions under which the pump is working; provides a mechanism wherein the lift of the water on the intake side of the pump is produced by the fall of the weighted members; and provides a mechanism the operation whereof is balanced to cooperate in the function of the pump.

HYDROSTATIC MOTOR.—J. G. MACMILLAN, Oakland, Cal. This invention has reference to hydrostatic motors, and has for an object the provision of a motor of this character with means so that the lifting force of water is concentrated and delivered at one point and readily converted into motive power for operating various power driven machines.

Prime Movers and Their Accessories.

PACKING FOR PISTON RODS OR THE LIKE.—G. H. ROBINSON, 93 Grace Church Street, London E. C., England. This invention pertains to packing for piston rods or the like, and the object is to provide a packing which, besides being capable of holding a thoroughly fluid tight joint, is easy to construct, capable of conforming to the shape of the piston-rod or other moving part in connection with which it is being used, and very durable.

ROTARY ENGINE.—W. ALEXANDER, 4 Rosenau Crescent, Battersea, London S. W., England. This invention has reference to fluid pressure engines (including air compressors, blowers and the like) of the rotary type in which there is an inner revolving or rotative drum, within an outer rotative drum or casing and in which abutments, hinged to the drum or casing, are arranged to move in the spaces between the inner and outer drums.

DAMPER.—L. SLIGHS, Indianapolis, Ind. In this instance the inventor provides an air inlet made somewhat upon the principle of an iris diaphragm, and so arranged as to be easily connected with the throttle and actuated by movements thereof, the iris diaphragm being also adjustable at the will of the operator for the purpose of varying its character.

Pertaining to Recreation.

AMUSEMENT APPARATUS.—A. E. WEST, Portsmouth, Ohio. Mr West's invention is embodied primarily in a pivoted circular platform adapted to oscillate vertically, and whereon a car or truck is adapted to travel, the required impetus being derived from the motion of the platform, which is produced by hand power, a spring, or any other form of motive power.

Railways and Their Accessories.

RAIL CHAIR AND BRACE.—O. PETERSEN, New York, N. Y. An object has been to provide means by which both the running rail and the guard rail can be securely positioned upon the tie, which permits the rails to be removed without displacing the chair itself, which tends to lengthen the life of the ties by obviating the necessity of pulling and driving the spikes or holding bolts in the removal of the rails and which obviates the necessity of providing drill or other holes in the rail webs.

MACHINE FOR GROOVING RAILWAY SLEEPERS.—F. ALTENSTEIN, Budapest, Austria-Hungary. This invention relates to machines for cutting into the upper surface of the sleeper or tie transversely disposed grooves to receive the tie plate and relates more particularly to machines in which the tables supporting the ends of the blank during working are first positively forced downward into their lowermost position in which the blank is pushed upon them, whereon each of the tables is raised by weights or springs for bringing the blank into the proper position relatively to the cutters.

Pertaining to Vehicles.

HOIST.—H. L. MCCOY and W. B. BOATRIGHT, Mathis, Texas. The intention here is to provide an easily operated device for the character specified for lifting vehicles, especially motor vehicles of considerable weight, by means of which the heaviest vehicle may be lifted with a small expenditure of force, and may be held in elevated position and without changing the relative position of the parts of the vehicle.

REED FOR MOTOR HORNS AND THE LIKE.—DOMINGO TERRA, 18 Rue des Rois, Paris, France. The object of this invention is to remedy numerous defects and it consists in providing a reed for motor horns and the like wherein the different parts can be detached with the greatest ease, either for cleaning purposes, or for restoring the curvature when damaged.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the inventor, title of the invention, and date of this paper.

NEW BOOKS, ETC.

THE SOCIAL DIRECTION OF HUMAN EVOLUTION. By W. E. Kellicott. New York: D. Appleton & Co., 1911. 349 pp. Price, $1.50.

In ministering to the welfare of the community, the philanthropist and social reformer, like the physician attending the individual, faces a double problem. First he must correctly diagnose the evil which he seeks to remedy. Once the trouble is recognized, and its nature properly understood, there remains the task of discovering or devising a suitable treatment. There have never been wanting those who have labored with self-sacrifice and in truly altruistic spirit for the good of the less favored strata of human society, and especially within the last century or so the systematic care for the sick and defective has developed to a stage of excellence which we may well witness with gratification. But while there can thus be no doubt as to the good motives which have been at work, the question has been raised, particularly by the advocates of "eugenics," whether some of the steps taken have not been based on a false or at least incomplete diagnosis of the trouble. It is pointed out that our asylums and hospitals and other philanthropic institutions, indeed, do a noble work for the individual, but that the benefit thus conferred is evanescent, lasting at best for a lifetime, and requiring ever renewed efforts in each generation. We are combating the symptoms, instead of seeking to eradicate the disease. Says the author

"If we could by education, by legislation, or by social effort, change the environmental conditions, would the race at once rise to a markedly higher standard of physique and mentality? Much, if not the whole battle for social reform, has been based on the assumption that this question can be answered in the affirmative. No direct investigation has really ever been made of the intensity of the influence of environment on man. To modify the obviously repellent was the immediate instinct of the more gently nurtured and controlling social class. Was this direction of social reform really capable of effecting any substantial change? Nay, by lessening the selective death rate, may it not have contributed to emphasizing the very evils it was intended to lessen?"

To show how intricate some of the questions involved are, new measures taken with the very best intentions may lead to wholly unlooked-for results. "We might point out that several movements apparently of high social value have been attended by a curious and largely unforeseen back action. Thus the enforcement of certain forms of employers' liability laws has led to discrimination against married persons by large employers of labor, and a premium thus put upon non marriage. The result of child labor legislation has been in some cases an enormous rise in the death rate of young children among the classes concerned, indicating that the children receive less care, now that they have ceased to be a prospective family asset, and have become chiefly a burden for many years. In other cases the result has been so serious a limitation in the birth rate that communities are dying out and factories are closing for want of workers."

There can be little doubt that the right standpoint from which to attack the problems involved is that of eugenics. In the volume under review the author brings before the reader in logical sequence the data, from scientific (biological) basis, and the "programme" of eugenics. Naturally much attention is paid to a discussion of the phenomenon of heredity, and Mendel's law of heredity has been given full scope. How terrible is the inherited bias for crime and ineptitude is shown by the records of the Jukes family of New York State. This family is traced back to 1720. Of 1,200 members whose history is known, 310 died in infancy. Of the remaining 900, 350 were professional paupers; 440 were wrecked by their own diseased wickedness; more than half of the women were prostitutes; 130 were convicted criminals, 60 habitual thieves, and 7 murderers! They cost the State over a million and a quarter dollars, and this cost is still going on.

These subjects are now, and rightly so, much in men's minds, and Prof. Kellicott's book is well calculated to form a valuable addition to the growing literature on eugenics. The value of works of this kind, which bring before the people at large the vital facts and principles of a topic of supreme importance, can hardly be over-estimated. In particular, Prof. Kellicott's book commends itself for its conciseness, the apt way in which the chief points are worked out and clearly laid down. The presentation is in every way attractive, and the book should prove interesting and most profitable reading to all classes.

HOW TO READ PLANS. By Charles G. Peker. New York: Industrial Book Company, 1911. 12mo.; 104 pp; illustrated. Price, 50 cents.

The writer answers the question, "How can I learn to read a drawing?" by saying that the best way is to learn to make a drawing. Architectural layouts in plan, elevation and section are simply illustrated and described, with an explanation of the various markings and instruction as to following to scale. The methods of designating walls, doors, columns, windows, the swing of doors, and so forth, is given, with a list of the symbols and abbreviations in use. There is a complete set of plans for a six-room frame cottage, and in conclusion the student is warned against some mistakes he is likely to make in his first attempts at plan-reading.

IDRAULICA. Ing. Dott. Edgardo Zeni Milan: Ulrico Hoepli, 1911. 16mo., 503 pp.

The handbook begins with a rather extensive bibliography of the subject, and follows this with the tables and formulas in common use. Other sections of the manual take up the various branches of the subject in logical order, leading the reader on from the constitution and properties of water and its behavior under natural conditions, to the principles and processes of hydrostatics and hydraulics. Two hundred and fifty engravings and a large insert add to the manual's attractiveness and enhance its value.

MANUALE DI LIVELLAZIONE PRATICA. Compilato da Mario Veglio. Milan: Ulrico Hoepli, 1911. 12mo., 130 pp., 47 illustrations.

A concise description of the various types of instruments in use, with their methods of application to the common exigencies and problems of field work.

CONCRETE WORKERS' REFERENCE BOOKS. By A. A. Houghton, New York: The Norman W. Henley Publishing Company, 1911. No. 3. Practical Silo Construction. No. 4. Molding Concrete Chimneys, Slate, and Roof Tiles. No. 5. Molding and Curing Ornamental Concrete. No. 6. Concrete Monuments, Mausoleums and Burial Vaults.

These booklets represent a part of a series of practical monographs on popular concrete subjects. The author's purpose has been to present not only the usual types of construction, but to fully explain and illustrate molds and systems that are not patented, which are equal in value and often superior to those restricted by patents. Each book is fully illustrated and the subject is treated in plain English.

UNSOUNDNESS OF MIND. By T. S. Clouston, M.D., LL.D., F.R.S.E. New York: E. P. Dutton & Co., 1911. 8vo., 360 pp.; 14 illustrations.

Unsoundness of mind is here treated in its very broadest aspect, for Dr. Clouston's book covers all that vast region, pathological, sociological, and pathological, that lies outside of the normal mind. Among the diseases which a physician might classify as those of a mentally abnormal person, he finds that can not be sharply defined from normal mental states. Because there is no reliable test between soundness and unsoundness of mind, the author has necessarily included in his book much that is particularly outside the line. The book as a whole is an excellent example of good popular scientific writing of a kind that will do much to enlighten the public on special problems which are only vaguely appreciated and to which a certain amount of odium is unfortunately attached.

THE BIRTH OF WORLDS AND SYSTEMS. By Prof. A. W. Bickerton. London and New York: Harper & Brothers, 1911. 16mo., 162 pp.

More than thirty years ago Prof. Bickerton published in the New Zealand Philosophical Institute a theory to account for the origin and life history of new stars. Prof. Bickerton's viewpoint that these celestial flashes result from the impact of two celestial bodies has been adopted by many scientists of note, chief among whom is Svante Arrhenius, who, in his book "Das Werden der Welten" and also review of his book before us. Although the theory is not yet generally accepted, it certainly explains in a most plausible way a number of astronomical phenomena that have long been puzzling.

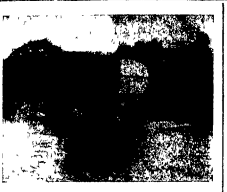
THE PRINCIPLES OF ELECTRO-DEPOSITION. A Laboratory Guide to Electro-Plating. By Samuel Field, A.R.C.Sc., F.C.S. New York: Longmans, Green & Co., 1911. 8vo.; 383 pp.; illustrated. Price, $1.80 net.

The writer believes that many who are interested in electro-plating are in need of a more thorough knowledge of fundamental principles. The opportunity of attending classes is by no means open to all, and the present volume is offered as at least partly filling the need of special instruction. An elementary knowledge of chemistry is taken for granted, details of shop practice are but briefly mentioned. The exclusive use of the metric system is not insisted upon. Apparatus, standard solutions, tools, and processes are explained at length and there is a comprehensive appendix of tables and general information.

GRAMMAR SCHOOL READER. Book One. By William H. Elson and Christine Keck. New York: Scott, Foresman & Co. 12mo.; 344 pp. Price, 50 cents.

The selections brought together within the covers of the Elson Reader are all old favorites. The arrangement follows an ascending scale of difficulty and literary quality, and there are review questions, words and phrases for study, and three fine biographical notes on the authors of the selections. We protest against the inclusion of "Casabianca" which has no poetic or literary value and has been parodied so often that it now appeals only to the child's sense of humor. If it carries any moral it must be to the effect that unintelligent obedience brings its own punishment.

Notes and Queries.



Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full limits to correspondents are not imposed from time to time and will be mailed on request.

(12529) F L R asks: What makes a horse hair when placed in still water wiggle like a snake? When one holds a hair of a horse in the hand it doesn't move a particle, but placing it in water starts the movement. What I would like to know is what furnishes the power for the movement? A. Any motion a horse hair may have when put into water is caused by its power to absorb water and to bend or twist as the water causes the hair to swell on the side nearest to the water. This will take place in the air. If you hang a long hair by one end and tie to the lower end a light rod of wood or a piece of straw or paper, the hair will bend so that it will twist back and forth from day to day.

(12530) C T C asks: In an air pump that drawn out 2 inches makes a practical vacuum, the outside air pressure is said to be 15 pounds to the square inch. Now suppose the piston to be drawn out to 4 inches and 6 inches and 8 inches, is the air pressure on the piston any more at 8 inches than it is at 2 inches? A. If there is no space whatever between the piston and cylinder head no "clearance," there will be a perfect vacuum (theoretically) behind the piston the instant after it commences to move, and an unbalanced pressure of 14.7 pounds per square inch on the opposite face of the piston, and this pressure will not increase as the piston is drawn out. In fact, the atmospheric pressure may be considered constant while the pressure behind the piston, equal to atmospheric at first, drops instantly as the piston begins to move.

(12531) H L W says: Can you lower the temperature of ice below 32 deg. F. if so what ratio will it bear? Supposing the temperature of the surroundings bear with the temperature of the ice? A. Ice like any other solid, takes the temperature of the place in which it is when that temperature is below its melting point. In a cold night when the temperature is at zero, a block of ice will cool to zero, just as the stones do and as rapidly according to some experiments, while others seem to show that it will cool less rapidly than the stones. Ice does not have the same properties of other solids. Its melting point is low as compared with most solids, and for that reason, we suppose people do not usually associate it with solids.

(12532) H C says: I read somewhere some years ago, that the moon possessed a satellite, but that it was so minute in diameter, occasionally visible. I have seen no other reference to it and cannot now place the reminiscence. Is this a fact? A. No satellite of the moon is known to exist. These statements are made in a book in the autumn issue. 2. Why do the etheric waves used in wireless telegraphy bend round the earth? Why do they not take their way through the other altogether irrespective of material bodies? A. The ordinary form of a wireless telegraph apparatus is equivalent to one half of a Hertzian oscillator, the other half of which is the earth. A complete Hertzian oscillator does give off waves which go through space like light, quite independent of the earth. A grounded oscillator gives off half waves, the lower part of which are not closed lines, but terminate in the earth, and cannot separate from it. They therefore follow the curvature of the earth's surface. They are also thought to produce or to be accompanied by alternating currents of electricity in the earth's surface. These electric currents must overcome the resistance of the material through which they are moving. This resistance will be less in water or moist earth than in dry materials, so that signals can be transmitted to a greater distance over water than over land. In the day time the air is rarefied by the sun, rendering it less moist, more opaque to other waves, thus rendering communication more difficult than in the night time. Both these well-known difficulties in wireless telegraphy are due to the fact that the etheric waves do not move as true waves in space, but employ the earth for one side of the wave as a material point of attachment. See Poincare and Vreeland's Maxwell's Theory and Wireless Telegraph, which we will send for $2.00 postpaid.

An interesting experience with Polarine

Saurer Motor Company
10 Church Street, New York

August 11, 1911

Standard Oil Company,
555 West 25th Street,
New York, N Y

Dear Sirs

It will probably be interesting for you to know that the "PIONEER FREIGHTER", the 4½ ton Saurer motor truck which has just finished the run between San Francisco and New York with a load averaging 3½ tons, used Polarine Oil, Transmission Lubricants and Grease

This was the most gruelling trip through which any motor vehicle ever passed

For twenty-seven consecutive days the truck was never off the low gear, 2·4 miles per hour, the engine running 1000 r p m Over the White Mountains of Arizona deep snow and mud were encountered in temperatures of down to zero, while through the desert sixteen days were consumed, most of which was on the low gear in temperatures of 140 during the day and never less than 100 at midnight.

This, you will agree, was a most trying test for the cooling system and the lubricating oils, but never once during this most trying trip was the engine overheated or the lubricating anything but perfect

Inspection of the cylinders and valves in Chicago and again in New York on completion of the trip totaling over 5,000 miles, showed them to be in perfect condition, and entirely free from carbon

The gear case in which we used Polarine Transmission Lubricant was opened only once during the trip for inspection and found to be in perfect condition

If there is any further information which would be interesting concerning this trip, we would be pleased to supply it.

Yours very truly,

H. D WATSON,
Eastern Sales Manager

Polarine

The Polarine Brand covers:

POLARINE OIL (in gallon and half gallon sealed cans, in barrels and half barrels), POLARINE TRANSMISSION LUBRICANTS, POLARINE CUP GREASE and POLARINE FIBRE GREASE.

These lubricants cover the needs of every part of the car.

Send to our nearest agency for "Polarine Pointers" which includes hints on the care of motor cars.

Standard Oil Company
(Incorporated)

The New British Dreadnoughts

(Concluded from page 230)

accommodation is 3,500 tons of coal with considerably over 1,000 tons of oil fuel in addition, the subsidiary engines are driven by steam and not by Diesel engines as in previous battleship-cruisers In spite of the high horse-power and heavy battery, sufficient proportion of weight has been found to adequately protect the ship against shell fire and submarine explosion The belt is of 9¾-inch Simpson steel thinning to about 4 inch at the bow and stern, leaving a space of 20 feet unprotected at the ends, the hull being minutely subdivided in lieu of the armor. The barbettes are of 11 inch plate, the hoods being 12 inch, a protected deck of 2¾ inches and subdivision by bulkheads is utilized on similar lines to the "Orion." The conning-tower is of a new and splinter-proof pattern, there being no apertures in the tower itself but a large dome-shaped projection rises from the rear of the roof provided with slots giving an almost all-round view. A second tower is situated aft of the after wireless telegraphy pole-mast

Taking into account the speed gun power, and protection of this ship, it is debatable whether the fighting power is not equivalent or superior to that of the "Orion" It must be admitted that the British Admiralty and their boards of construction have evolved in these ships war machines with an unprecedented potential power of destruction in view of the limitations imposed upon them by cost and displacement The ships now building or authorized ("King George V" and "Queen Mary" classes) are of the same general type as the "Orion" and "Lion," but improvements have added somewhat to the displacements What further perfection and also whether the limit of size has yet been attained in these huge ships can only be shown by the passage of time

Artificial Life

(Concluded from page 231)

of foam The microscope does not tell us all that we should like to know—and it tells us one thing at one time, and other things at other times It is quite possible that the "structure" of protoplasm is different in different organisms, or that it is different in different parts of the same organisms, or that it is different within the same cell under different conditions At any rate, Prof Butschli, to demonstrate his idea of the "alveolar" or foam-like structure of protoplasm, mixed some finely powdered potassium carbonate with olive oil that had been heated from 125 to 140 deg F The oil becomes partly saponified, producing an acid This acid reacts on some of the carbonate, producing minute bubbles of carbon dioxide Under the microscope a drop of this frothing mixture looks like a stock of protoplasm and the movements in it even resemble the streaming in a living cell

Some fifteen years ago these experiments were hailed by certain journalists as successful attempts to produce artificial life But no one who knows any thing about the problem, least of all Prof Butschli, thought that these experiments had anything to do with the creation of life The experiments were successful in the sense that they gave us a working model made of familiar materials, to help us understand the minute structures and movements within the cell How hard error does die is suggested by the fact that these experiments have been described over and over again in all grades of publications as a method for making "artificial protoplasm" until this very year

After the fact of cell-structure in organisms had become well established, one of the problems that interested the experimentalists was that of the growth of the cell wall, which to all appearances is not itself alive To test the theory that growth is produced by a stretching of the membrane with subsequent deposition of new material in the interspaces of the old wall, Moritz Traube carried on some very suggestive experiments He allowed a solution of sugar and gelatine to come in contact with a solution of tannin through the narrow opening of a small tube Now as soon as the tannin touches the gelatine it forms a membrane through which the water may easily pass, but through which the sugar cannot pass at all. The globule within the membrane continues to absorb water from the tannin solution by osmosis, stretching the membrane. The membrane *grows*, and under certain circumstances puts forth branches in various directions, the whole taking in the appearance of some weird plants or "sea weeds"

Traube's further experiments, from 1865 on, and those of others, extended our knowledge of osmosis, threw some side lights on the mechanism of the cell-growth, and furnished amusement to many persons, for these osmotic gardens are curious and somewhat mystifying But no biologist has in all these years suspected that Traube's phenomena were in any way related to "artificial life" until a few years ago Dr. Stéphane Leduc, professor of physics in the medical faculty of the University of Nantes, announced that he had discovered the physico-chemical foundations of life. He presented before the French Academy of Sciences a large number of demonstrations, in which he made "plants grow from artificial seeds" These seeds consisted of sugar plus some salt that would form a precipitation membrane with the substances of his growing medium For example, copper sulphate in a "seed" would cause growths in a solution of potassium ferrocyanide These growths were in no way different from those obtained by Traube and others, except that Leduc used a larger variety of substances in his experiments than had been used by other experimenters Anyone can make for himself a garden of such "artificial plants" with very little trouble Perhaps the easiest way is to place at the bottom of a jar a number of crystals of salts of heavy metals (e g, sulphates of copper, iron, zinc, cobalt) and carefully pouring over them a 10 per cent solution of sodium silicate or "water glass" The insoluble silicates of the metals will form the membranes, osmosis will cause them to stretch, variations in the density of the medium will cause irregular branching, and the colors of the salts within the membranes will give a further resemblance to "plants" (Fig 1 and Fig 1a)

Leduc went farther, however, and produced imitations of living structures down to the smallest details By placing a drop of colored salt solution into another solution of lower concentration, he produced "artificial cells" More definite cell membranes are produced by placing drops of 10 per cent solution of potassium ferrocyanide in a 10 per cent gelatine solution (Figs 2, 3) The appearance of nuclear division within a cell he produced by placing two drops of some solution near each other within another solution (Fig 4) That all these phenomena are due to osmosis or diffusion is well known to all physicists, that they are not in any true sense identical with "growth" and "nuclear division" may be known only to the student of biology Among other demonstrations made by Leduc in this connection was the formation of a "field of force" by the diffusion of liquids of different densities (Figs 5, 6, 7)

That the "artificial life" of Leduc had no real bearing on the fundamental physiological problems has been shown repeatedly, and Prof. Leduc has in later statements denied that he confused his phenomena with life processes, although his original confusion is on record in the proceedings of the Academy. Perhaps the best analysis of Leduc's results is that of Prof Maurice D'Hulin, director of the physiological laboratory at the University of Lille. This experimenter not only repeated all of Leduc's "demonstrations" but even showed that the various weird forms assumed by the "artificial plants" could be controlled by changing the concentration of the solutions, or by changing the proportions of the different materials used. Nevertheless we still find fairly frequent references to Leduc's overstepping the threshold between the non-living and the living by means of "artificial seeds."

In the spring of 1905 we had another "artificial life" sensation in the announcement that Mr. John Butler Burke, "of the Cavendish Laboratory of Cambridge University," had obtained some curious, life-like structures from the action of radium upon sterilized bouillon. Mr Burke was following up a sugges-

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

If you are not satisfied with your present business, write me today. T. H. Sutton, 76 Sherwood Ave., Louisville, Ky.

INQUIRY COLUMN

Inquiry No. 9244.—Wanted, addresses of parties having raw materials or mineral containing potash in any form.

Inquiry No. 9247.—Wanted, to buy a Parmelee celluloid waterproof.

Inquiry No. 9254.—Wanted, the name and address of manufacturers of lasts for boots and shoes, such as are used for printing an advertisement on.

Inquiry No. 9255.—Wanted, to buy a patent roller, a ball-bearing axle, which could be purchased on a roller bearing; it must be cheap and fully proved.

Inquiry No. 9260.—Wanted addresses of parties having Photolagraph reports. It take to duty one.

Inquiry No. 9267.—Wanted addresses of firms selling second-hand water turbines.

Inquiry No. 9268.—Wanted addresses of parties having gum materials to offer in any part of the world.

Inquiry No. 9269.—Wanted to buy a machine for removing the coating of a filament.

Inquiry No. 9270.—Wanted addresses of parties able to silk ornaments, garnet, agate, ebony or any material suitable as an exclusive.

this made many years before by Prof. E. Pflüger of the University of Bonn, that the essential difference between living protein and non-living protein lay in the fact that in the former oxidation or transformation of energy is *internal*, and that this internal oxidation could perhaps have been induced by cyanogen, a compound of carbon and nitrogen which was probably produced during the incandescent stage of the earth's history. Having failed to induce phosphorescence or other indications of the internal transformation of energy in organic substances by means of cyanogen, Mr. Burke resorted to radium

The test-tubes containing gelatine and beef-extract in the proportions used for bacteriological cultures were properly sterilized, and a minute quantity of radium chloride or bromide was added. The appearance of the gelatine changed, suggesting bacterial growths. Under the microscope there were seen tiny roundish bodies that increased in size, divided and moved about slightly! This was certainly life-like. In order to make sure that they were not bacteria due to contamination, the tubes were examined by Dr. Sims Woodhead, professor of pathology at Cambridge This authority declared they were *not* bacteria at all They were not even living things, for they dissolved in water; they disappeared entirely after standing in diffuse daylight for a little while, to reappear after a few days of darkness. Moreover, on being transferred to fresh bouillion, they did not increase in numbers

But the world was clamoring for artificial life; Burke could not lose so good a lead. Instead of calling his new discovery bacteria, which they were not, he called them "radiobes," implying that they were life-like things produced by radium. They were unlike any other living thing, so Burke set to work and elaborated a new definition of life, so that the radiobes could fit in Otherwise he should not have created "artificial life."

That the radiobes were not living things, in the accepted sense of the word living, must be obvious to nearly everyone But what are they then? Prof. Sir William Ramsay explains these structures are due to bubbles of hydrogen and oxygen gas (arising from the decomposition of water by the radium salt) and "radium emanation." The "growth" is due to the continuous production of more gas by further decomposition of water by the emanation within the bubble; the expansion of the gas might also lead to the breaking up of the bubbles into two or more (Fig. 8.)

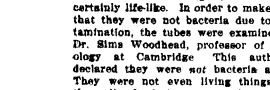

Fig. 8.—Radiobes in various stages of division. After Burke.

At any rate, the water-soluble radiobes are not alive, and it was later found that they could be produced in the bouillion by other substances besides radium, such as salts of barium, strontium, and lead. "Radiobes" produced by these substances also have "nuclei" consisting of insoluble sulphates of the metals used

The failure of scientists so far to produce "artificial life" is not to be charged against the science of biology. Very few of the attempt to produce "artificial life" have been made by biologists; who realise too well the complexity of the problems involved. The biologists will be satisfied for a number of years to come if they succeed merely in analyzing what goes on in a living cell, in terms of physical and chemical processes From time to time they will attempt to imitate a structure or a process by means of a working model; but they will not speak of artificial life until they are quite sure of all the conditions that play a part in this most intricate of phenomena.

The Solar Constant.—In the *Proceedings of the American Philosophical Society*, May-June, 1911, Mr. C. G. Abbot defines the solar constant as "the number of degrees by which one gramme of water at 15 deg. C. would be raised, if there should be used to heat it all the solar radiation which would pass at right angles in one minute through an opening one centimeter square, located in free space, at the earth' mean solar distance." Experiments were begun about 1835 by Pouillet and Sir John Herschel for the measurement of this great constant of nature, and the investigation has been continued by Forbes, Crova, Violle, Radau, Langley, K. Angström, Chwolson, W A. Michelson, Rizzo, Hansky, Scheiner, Abbot, Fowle, and others. The difficulty of the problem is shown by the fact that until a few years ago entire uncertainty prevailed as to the value of the solar constant, between the limits of Pouillet's value, 1.76 calories, and Angström's value, 4.0 calories per square centimeter per minute. The author and his colleagues have made over 400 observations with special apparatus, including the silver-disk pyrheliometer, an absolute water-flow pyrheliometer, and the recording spectro-bolometer, at Washington, Mount Wilson and Mount Whitney, to determine the value of the solar constant and its possible fluctuations; and they now announce a mean value of 1 922 calories, which may prove to be 1 or 2 per cent too low, as the observations have been made mainly near the time of sunspot maximum, and hence of diminished radiation This value is, moreover, subject to fluctuations amounting to about 8 per cent, at irregular intervals of a few days, and these fluctuations are thought to indicate a true variability of the sun itself In other words, the solar "constant" is probably variable

The Current Supplement

WE have previously had occasion to refer to the fact that the United States Post Office is finding it economical to do some of its own printing, instead of giving out the work to contractors, as heretofore In the current issue of our SUPPLEMENT, Mr Gunnaway describes the arrangements which have been made for printing money orders on the government's own presses—In the second installment of his article on the Great Star Map, Prof Turner deals with the subject of "Star Counting" A note on the Variation in the Purchasing Power of Gold should prove of general interest — We like to keep track, not only of progress at home, but also of the course of events abroad An article on the electrification of suburban lines in the British capital is published with this subject in view—We have seen the automobile invading a great variety of fields of usefulness. The motor car to the rescue is the modern cry when fire threatens property and life, as is illustrated by an article on a new auto-fire-engine —The article on Practical Aspects of Printing Telegraphy reaches its seventh instalment in this issue —The Mechanical Handling of Freight is a most important technical problem, to the study of which new contributions are added every day One example of this is shown in an illustrated article—Factory Economy is the guiding principle ever before the eyes of the works superintendent. A description of an immense superheater utilizing waste heat and installed in one of the plants of the United States Steel Corporation is interesting in this connection —An article from the pen of the great scientist Prof Wilhelm Ostwald, on the Biology of the Savant, brings us one of his lucid studies in the psychology of great personality — The extraction of crude cocaine and its refining process is described in an article derived from the *Engineer*.

Materials for Paper Money

THE materials that go to make up our paper money are gathered together from all parts of the world. Part of the paper fiber is linen rag from the Orient. The silk comes from China or Italy. The blue ink is made from German or Canadian cobalt. The black ink is made from Niagara Falls acetylene gas-smoke, and most of the green ink is green color mixed in white zinc sulphite made in Germany

The red color in the seal is obtained from a pigment imported from Central America.

$500.00 for This Simple Invention

Perhaps some reader of the SCIENTIFIC AMERICAN can help us to solve this problem:

We control 92% of the oyster beds from which genuine Blue Point oysters come.

Because no one has ever trade-marked oysters, substitution and fraud are easily possible.

How can we mark the shells of our Blue Point oysters so that the consumer can be sure that he is getting the genuine and not a substitute?

The marking must be accomplished without hurting the oyster, or detracting from its flavor or attractiveness.

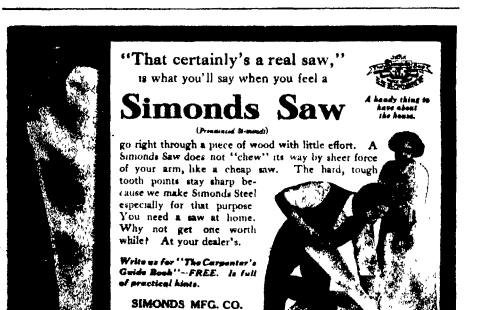
It must be of a nature that will show on both upper and lower shells and that will withstand the water incident to handling the oyster

It must be so distinctive that we can prosecute frauds those who advertise and offer Blue Points without this mark.

The whole cost of trade-marking oysters must be less than 25c a barrel—which contains from 800 to 1800 oysters.

We have thought of dipping the point of the oyster in blue plaster of Paris, and of sand-blasting two lines across both shells—but we have never worked either of these methods out

To the inventor who devises a method which we can adopt we will pay $500 in gold.



To the inventor who furnishes us with an idea, not complete in itself, but which enables us to perfect a method, we will make a suitable reward.

You can easily get oyster shells to experiment with Send your solution to

SEALSHIPT OYSTER SYSTEM, 40 Central Street, BOSTON, MASS.

POWER SERVICE
AT SMALLEST COST

To insure certain of your power buy a dependable, economical, powerful, and thoroughly efficient I H C Gasoline Engine. Maximum power with a minimum fuel. Simple, reliable construction, smooth running, built right, work right

IHC
GASOLINE ENGINES

—deliver full rating of power. Select one for your needs—you can't go wrong with an I H C. Thousands of users everywhere know I H C Gasoline Engines are the best to buy. Made in many styles and sizes from 1 to 35-H P—vertical, horizontal, stationary, portable; air or water-cooled, and from 2 to 45-H P. Write for complete I H C catalogue. Address

Get into the automobile business without any investment

We will teach you to get into the automobile business. More than 100 different men used a new garage and automobile repair shop. We are for you a sales agency that puts you $1000 to $5000 cash per year. We supply all necessary tools. Under our plan you learn the business, establish a business and make money while learning. For begin the second month. Write for Free Book. Tells how a man and can find right in a factory where you can learn. We furnish you a position the day you start a contract with you we will for you if you do not get position. Write for Free No. 107 and handsome catalogue telling about getting started in this wonderful automobile business.

The Automobile College of Washington, Inc., Washington, D. C.

EASY TO BUY $10 down and $10 a month

Our monthly payment plan makes it easy for anyone to have the best heating system. Buy direct and save the dealer's big profits and excessive charges for installation and repairs. Saves one-third the cost.

JAHANT Down Draft FURNACE

For residences, schools, hotels, churches, etc. Sold Under a Binding "Guaranty Bond" to give perfect satisfaction after Roll Grates" use or money refunded. We send complete Down Draft Furnace, Registers, pipes, special blue print plans, full directions and all tools for installing. So easy to install a boy can do it.

OUR FREE CATALOG
Explains the patented Down Draft System fully and tells why it gives more heat and saves half the cost of fuel. Write for it now.

Aeronautics

A New World's Record Flight With a Passenger.—Besides the new height record made by Beachy at the Chicago meet, Wm Beatty set a new mark for endurance with a passenger by remaining aloft with Fred Wagner, a photographer of the Chicago Tribune no less than 3 hours, 42 minutes, 22 1/5 seconds. The new record beats by 23 minutes that made by Amerigo with an Aviatik aeroplane in Germany some time ago. Beatty accomplished the feat with a Wright biplane.

Aerial Postal Service in England.—The English Postmaster-General has arranged for the inauguration of the "First United Kingdom Aerial Post" in London on September 9th. The aerial mail will be collected from special letter boxes located in several department stores. It will be taken by automobile to the Hendon aerodrome, whence an aeroplane will carry it to Windsor Castle in less than half an hour. From the post office at Windsor Park the letters will be sent in the regular way to all parts of the world.

Flying in a Wind.—Perfect mastery of their machines in half a gale by the Curtiss aviators, Beachy, Ely and Ward, and the ability to fly and climb to great heights when even the Wright machines were unable on account of the wind, was the surprise of the Chicago and Boston meets. At the former Beachy and Ward flew high and long—the former attaining and altitude of 7,017 feet and flying till his fuel was exhausted—when five Wright machines remained on *terra firma*, while at Boston Beachy and Ely made fine flights after the 23-mile race to the lighthouse and back had been postponed on account of the wind.

Aviation in the Sahara.—The French government is pushing forward its plans for providing communication by aeroplanes in the Sahara, especially for military purposes. In accordance with the recommendation of the military committee of the Ligue National Aérienne, and of General Bailloud, commanding the 19th army corps, a post for aeronautical studies will be established in the autumn of 1911 at Biskra, 140 miles from the coast. Particulars of this enterprise have been published in *La Nature*, from which it appears that five aeroplanes will be provided, four of them to be of metal, in anticipation of the fact that wooden apparatus would be seriously warped by the hot climate. The staff will consist of three aviators, under the command of Lieut de Lafargue, and thirty other men (mechanicians, etc.)

A New Record for the Michelin Cup.—Competition remains for the Michelin Trophy, which is to be awarded this year for the longest continuous flight over a 62-mile circuit. Stops are permissible to take on fuel, etc., the thing that counts being the distance covered from the start to the finish of the attempt. On the 9th of last month Vedrines set out to fly 1,000 kilometers (starting at 4 03 A M, he flew until 3 P M on his Morane monoplane, covering 811 2 kilometers (503¾ miles) of which 800 kilometers (496.8 miles) count as the record. The time, including two 50-minute stops, was 10 56'42, and the average speed 57¾ miles an hour. On the 26th ult. M. Helles, in a 15-hour flight, covered 1,200 kilometers (745.6 miles) on a Nieuport monoplane that averaged 50 miles an hour including stops.

Recent Altitude Records.—Beginning with the record height of 3,300 meters (10,826 feet) scored by Capt Felix a month ago, a number of altitude records have been made with and without a passenger. Capt Felix, who flies a Blériot, made his record when practising for a flight across the Alps. On the 4th ult., in France, Lieut. Biard started from Mourmelon with a passenger and attained a height of 2,000 meters (6,560 feet) over Sissonnes. The same day, in England, Olivet de Montalent reached 2,500 meters (8,200 feet) with a passenger. On the last day of the Chicago meet Lincoln Beachy broke the world's altitude record by climbing to a height of 3,548 meters (11,640 feet) in one hour and 48 minutes. He attained this great height in a Curtiss "headless" biplane, and thrilled the spectators by a daring descent in spirals after his gasoline was exhausted. Beachy's actual height above sea level was 12,296 feet.

Science

Prof. Tarr's Adventures in Alaska.—According to press dispatches, Prof. Ralph E. Tarr, of Cornell University, who has been studying Alaskan glaciers, lost all of his data and instruments when a skiff, in which he and his party were crossing the delta at Fairbanks, capsized.

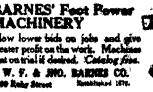
The German Antarctic Expedition.—The "Deutschland," the ship of the German Antarctic Expedition, which sailed from Germany in May, is expected to reach Buenos Aires in September. A leisurely voyage has been made over parts of the Atlantic that have hitherto been little explored in a scientific way, and oceanographic and physical observations have been carried on. Lieut. Filchner, the commander of the expedition, will join the ship at Buenos Aires, together with the last part of the equipment, including the ponies and dogs.

An International Museum of Speleology is to be founded at Adelsburg, Austria, near which lies the Adelsburg Grotto, the largest known cavern of Europe, the passages of which are five and one-half miles long. In this museum will be collected objects of all kinds relating to the study of subterranean botany, zoology, paleontology, anthropology, as well as geophysics, underground waters, etc. The site, which is in the famous Karst country, is well chosen for the purpose. The Austrian Ministry of Agriculture has contributed $6,000 to the undertaking.

A New Aerotechnic Institution.—Notwithstanding the fact that the word "aerotechnic" is not yet known to the dictionaries, institutions devoted to aerotechnic investigations are springing up in all parts of the world. The latest addition to the list is the Aerotechnic Institute, near Versailles, founded by M. Deutsch de la Meurthe, which, we learn from *Nature*, was formally opened on July 6. It has been endowed by its founder with a capital of $100,000 and a yearly income of $8,000, and is equipped with all apparatus necessary for experiments in aeronautics and aviation.

Why American Prairies are Treeless.—Prof B. Shimek, of the State University of Iowa, has been studying this question in Iowa, where the treeless prairie originally covered more than seven-eighths of the total area of the State. He finds that the absence of trees is not due primarily to the soil or the topography, nor to such causes as prairie fires, the former abundance of the bison, etc., but is an effect of climate. Moreover, it is not due to a deficient rainfall, so much as to an excessive rate of evaporation. "The prairie areas are uniformly so situated that they are fully exposed to the factors which cause rapid evaporation, namely, the sun and the wind. During much of the year they may present conditions quite favorable to plant growth, but there are seasons and there are portions of the year, especially in midsummer, when evaporation and consequent desiccation become so extreme that only those plants which are especially adapted to dry regions can survive."

Petrified Forest Giants.—Three petrified redwood trees, that have been pronounced the very largest in the world—that have thus far been discovered—have just been uncovered from the débris of the mountain-side—only a short distance from the famous Bohemian Club Grove, in Sonoma County, Cal. This point is near the little town of Occident. One of these prehistoric monsters—that make the pyramids of Egypt modern, by comparison, in their ages, measures 23 feet in diameter and is 350 feet in length! The other two petrified trees are 18 and 12 feet in diameter, respectively. The very largest petrified trees yet discovered, near Calistoga, Sonoma County, Cal., is only 12 feet in diameter. These three trees lie on a wooded hill pointing due north and south. The petrifaction is most remarkable—the grain of the wood, and in one of them the decaying heat, being very plainly discernible. Surrounding these petrified trees is standing a forest of very large redwoods. However, all of the standing trees are dead. The owner of the land on which these three great petrifactions lie, is now having the débris all cleared away, so as to fully expose the giant trunks, and an iron railing will protect them.



THE SEBASTIAN 18-INCH ENGINE LATHE
Lead Screw
Automobile Builders, Garages, Repair Shops and Jobbing Shops find this the ideal lathe for their work. Catalog free. The Sebastian Lathe Co. 120 Culvert St., Cincinnati, Ohio.

Electricity

Connecting England and Belgium by Telephone.—Arrangements have been made to lay a submarine telephone cable across the English Channel to connect England with Belgium. The length of the cable will be close to 50 miles. It will be provided with Pupin coils, and the construction will be similar to the cable now connecting France with England.

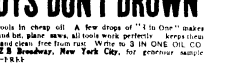
Wireless on Turkish Warships.—A wireless telegraph station is soon to be built at Constantinople. This will have a capacity of twenty kilowatts, and a radius of six hundred miles. In connection with this station, eleven Turkish warships will be equipped with apparatus covering a radius of four hundred miles, and seven others will be equipped with less powerful apparatus.

A Monorail Elevated Road for Mexico City.—A corporation is seeking permission to build an elevated railway in the Federal District, Mexico, on the plan of the one in Berlin, where the cars hang from a single rail It is proposed to build a loop or circle within the city proper, by which passengers will be carried to within three blocks of almost any part of the capital, and from this loop branches will extend to the suburbs The branch lines will run at ground level after leaving the city.

Wireless Telegraphy in Morocco.—A wireless telegraph station recently installed at Fez has greatly facilitated communication between the French government and its troops in Morocco Messages are sent from the Eiffel Tower in Paris to Oran, Algeria, and there relayed to Fez Another wireless telegraph station has been established by the French at Taourirt This furnishes an alternate means of communication between Paris and Fez, viz., by submarine cable to Oran, by overland telegraph to Taourirt, and by wireless to Fez.

Electric Baling Presses.—It has been an almost universal practice to operate baling presses by hydraulic power This has entailed considerable expense in localities where water pressure could not readily be obtained. It was recently suggested that electricity could be used to advantage for this purpose Presses of this sort are now in operation The table which carries the bale is suspended by means of four steel cables from the press head. The cables pass over several sheaves, to the winding drum which is connected to a reversible motor By this means the table is pulled up toward the press head, compressing the bale An automatic brake is provided for holding the bale under pressure.

Wireless in Military Aviation.—On July 29th the new wireless outfit of the French military aviators was used with entire success in an aeroplane manned by Adjutant Ménard, as pilot, and Lieut. Brenot, according to a note in *Cosmos* The aviators started from St Cyr and flew over the region of Rambouillet. Keeping at an altitude of 1,600 feet, they had no difficulty in sending wireless messages to the Eiffel Tower, at an average distance of thirty miles, whence the messages were immediately transmitted to the Ministry of War The apparatus used weighs, in all, 48 pounds The spark is produced by a magneto operated by the motor of the aeroplane The antenna, made of steel wire, can be rolled up when not in use. Experiments are now being made with a view to increasing the range of transmission



Wireless "Lighthouses."—*La Nature* announces that the French Ministry of Public Works has decided to establish three "phares hertziens" The transition of this expression into English involves a contradiction; a "phare" is a lighthouse, but the new installations are to utilise Hertzian waves in lieu of light, and are designed to take the place of ordinary lighthouses in time of fog. One will be established at the lighthouse of Créach, Ushant; one on the island of Sein; and the third on the lightship "Le Havre," seven miles from the cape of La Hève. Each of these three "lighthouses" will send a characteristic signal By the use of the Bellini-Tosi radio-compass vessels will be able to determine the direction from which the signal comes, and thus get their bearings in thick weather.

No-Rim-Cut Tires
For 800 Cars Per Day
When our factory additions now under way are completed we shall have capacity for 3,300 Goodyear tires per day. More than enough to completely equip 800 cars each day.
This year, with six times the output of 1909, the demand has run ahead of supply.
All because motor car owners are proving that these patented tires do cut tire bills in two.
These tires can't be rim-cut. And they are 10 per cent oversize. This oversize alone, with the average car, adds 25 per cent to the tire mileage
They cost no more than standard old-type tires, so the saving is clear They fit any standard rim.
These tires, naturally, are being adopted as fast as men find them out.
Our Tire Book—based on 12 years of tire making—explains all the advantages. Ask us to mail it to you

Valuable Books
Industrial Alcohol Its Manufacture and Uses
By JOHN K. BRACHVOGEL, M.E. Octavo, 528 pages, 107 illustrations Price, $4 00
¶ This is a practical treatise, based on Dr. Max Maercker's "Introduction to Distillation" as revised by Drs. Delbrück and Lange. It contains new materials, making, working and yeast preparation, fermentation, distillation, rectification and purification of alcohol, alcoholometry, the value and significance of a test-free alcohol, methods of denaturation, its utilization for light, heat and power production, a statistical review and the United States law. The is one of the most authoritative books issued on the subject and is based upon the researches and writings of the most eminent of Germany's specialists in the business of fermentation and distillation. It covers the manufacture of alcohol from the raw material to the final rectified and purified product, including chapters on denaturing, domestic and commercial utilization
Handy Man's Workshop and Laboratory
Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations Price, $2 00.
¶ This is a compilation of hundreds of valuable suggestions and numerous ideas for the mechanic and those mechanically inclined, and tells how all kinds of jobs can be done with home-made tools and appliances. The suggestions are practical, and the solutions to which they refer are of frequent occurrence It may be regarded as the best collection of ideas of resourceful men published, and appeals to all those who find use for tools either in the home or workshop. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.
Concrete Pottery and Garden Furniture
By RALPH C DAVISON 16mo., 196 pages, 140 illustrations. Price, $1 50
¶ This book describes in detail in a most practical manner the various methods of casting concrete for ornamental and useful purposes. It tells how to make all kinds of concrete vases, ornamental flower pots, concrete pedestals, concrete benches, concrete fences, etc. Full practical instructions are given for constructing and finishing the different kinds of molds, making the wire forms or frames, selecting and mixing the ingredients, covering the wire frames, modeling the cement mortar into form, and casting and finishing the various objects. With the information given in this book, any handy man or novice can make many useful and ornamental objects in cement for the adornment of the home or garden. The information on color work alone is worth many times the cost of the book.
The Design and Construction of Induction Coils
By A. FREDERICK COLLINS. Octavo, 295 pages, 159 illustrations. Price, $3.00.
¶ This work goes in minute details full practical directions for making eight different sizes of coils, varying from a small one giving a pencil-inch spark to a large one giving twelve-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the operations are written in language easily comprehended. Much of the matter in the book has never before been published, for instance, the various drying and impregnating processes, the making of adjustable core condensers, the construction of make-and-break vibrating switches, the set of complete wiring diagrams, etc. The illustrations have all been made from original drawings, which were made especially for the work.
Any of these books will be sent, postpaid, on receipt of advertised price

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty-Eighth Edition of
"The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by ALBERT A. HOPKINS, Query Editor of the Scientific American

THIS is practically a ***new book*** and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters: I. Accidents and Emergencies. II. Agriculture III. Alloys and Amalgams. IV. Art and Artists' Materials V. Beverages; Non-Alcoholic and Alcoholic. VI. Cleansing, Bleaching, Renovating and Protecting. VII. Cements, Glues, Pastes and Mucilages VIII. Coloring of Metals, Bronzing, etc. IX. Dyeing X. Electrometallurgy and Coating of Metals. XI. Glass XII. Heat Treatment of Metals. XIII. Household Formulas XIV. Ice Cream and Confectionery XV. Insecticides, Extermination of Vermin XVI. Lapidary Art, Bone, Ivory, etc. XVII. Leather. XVIII. Lubricants. XIX. Paints, Varnishes, etc. XX. Photography XXI. Preserving, Canning, Pickling, etc. XXII. Rubber, Gutta-Percha and Celluloid XXIII. Soaps and Candles XXIV. Soldering XXV. Toilet Preparations, including Perfumery. XXVI. Waterproofing and Fireproofing XXVII. Writing Material. Send for detailed illustrated prospectus.

Octavo (6¾ x 8¾ inches), 1077 Pages, 200 Illustrations

AN IDEAL MAGAZINE FOR THE IDEAL HOME

American Homes and Gardens

gives its readers the experience of experts in solving the most difficult home problems. It is a thoroughly practical magazine, having the word *home* for its keynote

How to Build the Home

Floor plans and details of construction of houses of moderate cost as well as more pretentious mansions are a feature of each issue.

How to Decorate the Home

The most experienced decorators in the country describe how the best and most artistic results are attained from the point of expenditure and the more important one of satisfaction.

How to Plan and Lay Out the Garden

The frame of the house-picture is the garden, and success in its treatment means that each tree and shrub is correctly placed as well as properly grown, hence this department will be found most helpful.

Outdoor Life and Amusements, Articles on House Industries

Every phase of country life is authoritatively discussed from month to month in its pages. American Homes and Gardens is conceded to be the handsomest magazine published in America. Its beautiful cover printed in colors changes each month, and is always a work of art. Subscription price, $3.00 per year.

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING, B.Sc., A.M., C.E.

CRITICISM

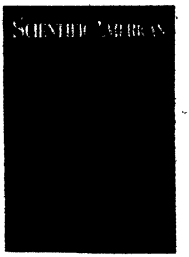
"The first treatise upon aviation which we have seen which may be styled really complete. . . . . Actual aeroplane designing is the central theme of the volume. . . . . The prominent types are exhaustively compared. . . . . The illustrations are a notable feature."
—*Rochester, N. Y., Chronicle.*

"A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplanes. . . . . Presents in compact shape the substance of aerodynamic theory . . . Easily comprehensible to the reader who can concentrate his attention . . . . . It is the most scientific popular book on the aeroplane that we have come across so far."
—*New York Sun*

"Many writers have failed to realize the demand which exists for aero literature in which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the entire subject. For a writer to steer a straight course between the mazes of trigonometry on the one hand, and the superficialities of mere discussion in a popular vein on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who can sufficiently divorce himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and informative to the less erudite seeker after knowledge."
—*Phila. Inquirer*

"Students learned in aerodynamics and laymen ordinarily interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have realized the future of aerial navigation, and desire a work treating solely of the heavier than air machines written by an acknowledged expert and with no hobbies hidden in the discussion."
—*Boston Journal.*

"While enthusiastic in his interest as becomes one who has written so superb a volume, Mr. Loening is also rigidly accurate as the most exacting scientist could demand. Here is a work which is at once a history and textbook which may be depended upon for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once new and authoritative with reference to the entire subject and that it is practical in the highest degree is the just praise due to this volume."—*Buffalo News.*



"Mr Loening has written, in fact, for the man who wishes to apply practically the experience that has already been gained."
—*New York Times.*

12mo (6x8¼ inches) 340 Pages, 278 Illustrations. Attractively bound in cloth
Price $2.50 net, postpaid

Industrial Chemistry

The September Magazine Number of the SCIENTIFIC AMERICAN issue of September 16th, 1911

In the Scientific American for September 16th, the debt of humanity to the chemist will be set forth in simple language by men of the highest authority. No book of fairy tales ever told a story more amazing than that of modern industrial chemistry.

Just now one of the most puzzling of Nature's laboratory secrets has yielded to the patient research of the chemist. Rubber can actually be made artificially. But the product is more precious than diamonds. Will artificial rubber ever be a commercial possibility? This subject is discussed by Ira Remsen, President of Johns Hopkins University, in simple non-technical language.

A surprising laxity has been shown in this country in the matter of buying raw materials. Fortunately, we are waking up to the fact that enormous savings may be made if such materials are subjected to thorough tests. On this subject Dr. Charles F. McKenna, a leading expert, has prepared an interesting article.

America can point with pride to its achievements in electrochemistry. What the chemist can do with the aid of electric energy is told by William H. Walker, Professor of Chemistry at the Massachusetts Institute of Technology.

The opportunities for achievement offered by Industrial Chemistry will be discussed by Robert Kennedy Duncan, Professor of Industrial Chemistry at the Universities of Pittsburgh and Kansas. He will also give valuable advice to young men who wish to enter this field.

Dr. Allan Rogers, of Pratt Institute, is going to explain how he trains men to become foremen in works employing chemical processes, thus making for an intelligent cooperation with the expert chemist.

The familiar platinum sponge igniter for gas jets represents one of the infinitely numerous examples of so-called contact action of catalysis. Of the significance of this phenomenon and the mystery still surrounding it, which science has as yet been unable to dispel, Mr. A. J. Lotka writes in a specially prepared article.

MODERN ALCHEMY

"VANADIUM" "MASVAN"

More important than the quest for the Philosopher's stone is the aim of modern science toward the making of perfect steel.

Chemistry gave us a knowledge of Vanadium; commerce furnished us a plentiful supply of Vanadium ores, and metallurgy perfected the application of Vanadium Alloys.

In an age of alloy steels, Vanadium is the *Master Alloy*. And this is why:

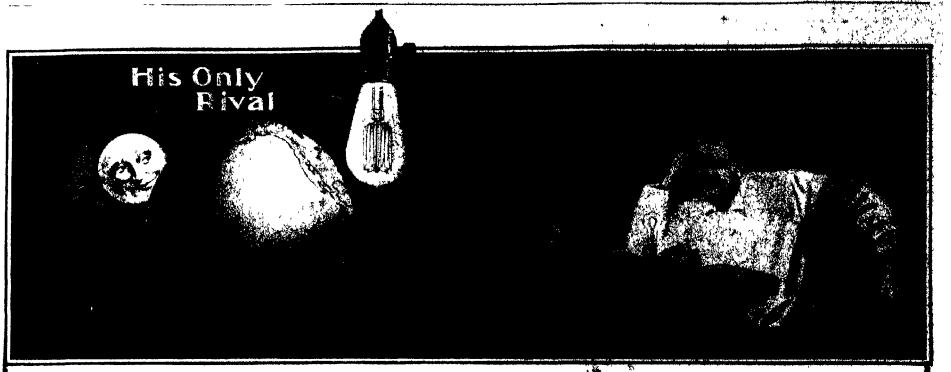
MANUFACTURE. Vanadium Steel is easy to make. It can be produced without inconvenience in the open hearth furnace, crucibles, or the foundry ladle

RANGE. There are many standard types of Vanadium Steel now on the market—a type for every broad class of high grade service. Special types are made for special purposes.

MACHINING. Vanadium Steels present no difficulty to the machinist.

FORGING. Vanadium Steels forge readily, under hammer or die

DUCTILITY. Vanadium is the only element that increases tensile strength and elastic limit without great reduction of ductility



STRENGTH. Combined with nickel or chromium or both, Vanadium makes the most rational, strong steel known. By rational is meant a steel that is strong without being brittle, resilient without weakness, hard without being refractory, close grained, tough, and subject to accurate modification by suitable heat treatment.

LIFE. Extraordinary durability results from the influence of Vanadium as a component part of steel. Weakness due to segregation or the occlusion of gases and oxides is minimized. The result is steel that is strong, homogeneous, non-crystallizing, tough, durable and good all through. Try other steels—for trial, but use Vanadium Steels for long life, hard service and safety. Booklets

American Vanadium Company

331 FRICK BUILDING, PITTSBURGH, PA.

Thirty-two years ago the Wizard of Menlo Park dreamed his great dream which has now come true—Electric Light for Everybody.

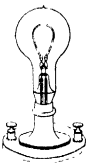
Edison's Dream Comes True

When Edison invented the electric incandescent lamp thousands journeyed to Menlo Park to see "the light that burned without air."

Edison put a little paper horseshoe filament, that he had carbonized, into a glass bulb and pumped out the air. Next he passed a current of electricity through this horseshoe.

The Dream

It glowed white hot, lighting up the darkened room, another light glowed in his face, for he saw the revolution that tiny bulb would bring about in the world's useless hours.



But the first lamps of 16 candlepower used up 100 watts of electricity.

Slowly, as improvements came, the amount of light was increased. Six years ago people thought the limit was reached, for the close of the first quarter-century of Electric lighting was celebrated by the advent of the Edison Gem lamp. Using the same amount of electricity, it gave more than twice the light of that first wonderful lamp.

The Revolution

Suddenly another invention in electric lamps revealed the dawn of a new era in electric lighting—unseen in the dreams of anyone—except Edison.

This was the Tungsten filament lamp which instead of the original 16 candlepower—or the fancied limit of 40 candlepower—gave actually 80 candles of light from the same 100 watts.

Edison's Original Lamp Invented 32 Years Ago

Latest Edison Mazda Lamp with Non-fragile Filament

This lamp almost materialized the Dream—but the filament was brittle—and the cost was high.

Both these obstacles are now cleared away. First, a brilliant invention has resulted in the production of a drawn wire stronger than steel. This wire is used to make the filaments in Edison Mazda lamps.

The filament or "burner" in Edison Mazda lamps is so sturdy that hundreds of thousands are in use under severe and trying conditions, even for lighting railway trains and automobiles.

Next—of prime importance—the full advantage of the General Electric Company's reduced cost of manufacture has been given to the public.

And the present price of the perfected Edison Mazda lamp is about one-half that of the first, brittle tungsten lamp.

The Dream Comes True

So, with lower cost and a better lamp, Edison's dream of the Sun's Only Rival has come true. The waiting millions can be served now that electric light costs so little and does so much.

Now, you can have Electric Light in your home, your office, your store, your factory at a price you have been waiting for, if you use the latest invention—Edison Mazda Lamps, made only by the General Electric Company.

Buy these Lamps and see how Edison's Dream has come true for you.

Sold by Electric Light Companies and Dealers everywhere.

How Electricity is Aiding the Chemist

Some Principles Underlying the Application of Electricity to Chemistry

By Prof. William H. Walker, Massachusetts Institute of Technology

RAW material and energy, these are the two essential factors which go to make up every industrial chemical process. With the exception of the rare gases of the atmosphere, every object around us is susceptible of chemical change, and hence available to a greater or less extent as raw material for some chemical process. The possibilities of the chemist are in this direction unlimited. The second factor, energy, was for many years supplied almost exclusively in the form of heat derived from the combustion of some kind of fuel, and thus limited in many ways the chemist's activity. It is only within the last quarter of a century that there has been supplied to the manufacturer in commercial quantities, a new form of energy, namely, electricity. With the development of powerful electric generators harnessed to great sources of water power there has been rendered available a form of energy destined to play an important part in the industrial development of the country. When chemical change is brought about by the application of electric energy, we have an electrochemical process, and the art is called electrochemistry.

It would have little value simply to catalogue the many successful applications of electrochemistry which have been worked out, or to describe the great industrial plants based on electrochemical processes which have grown up in America within the last decade. Rather we will attempt to point out some of the principles underlying the application of electricity to chemical industry, and to give a few examples illustrative of each general class.

Electric Conductance and Decomposition.—When a chemical substance such as common salt or blue vitriol is dissolved in water, it is, for the most part broken up or separated into electrically charged atoms or groups of atoms called ions. When a current of electricity from some external source is led into such a solution, it is transported through the solution by these ions. At the points where the current enters and leaves the solution (i. e., the electrodes) these ions are deposited and take from the current the electrical energy necessary to change them into the corresponding elements or compounds. Thus when an electric current is passed through a solution of blue vitriol (copper sulphate) metallic copper separates out where the current leaves the bath, and sulphuric acid is formed at the other, or entering, electrode. This ability of the electric current to decompose chemical compounds into their constituent parts is called electrolysis, and forms the basis of many important industries.

Electrolysis of Salt.—Common salt, sodium chloride, is one of the cheapest as well as one of the most important of our chemical raw materials. From it through intricate and expensive processes there has been made for centuries the caustic soda and soda ash used in a hundred industries, such as the manufacture of glass, soap and textiles. At the same time from this salt by another complicated process the bleaching powder of commerce was produced. Electrochemistry has changed all this. At present by simply passing a heavy current of electricity through a strong salt solution, caustic soda is produced and drawn off at one electrode, and chlorine gas, which when absorbed by common lime makes bleaching powder, is evolved at the other. Compared with the older processes, this electrolytic one is simplicity itself. Although there are many millions of dollars invested in the old processes the time is rapidly coming when they must give way to the new.

In a very similar way, namely, by passing a current of electricity through a hot solution of potassium chloride (the "muriate" of commerce) and allowing the two products formed at the electrodes to react on each other, is formed the potassium chlorate used in such large quantities in making all kinds of matches. This electrolytic process is carried on at a number of places in the United States and has entirely superseded the old method of making this important chemical.

Refining of Metals.—On this same principle depends the enormously important industry of the electrolytic refining of copper, by which during last year alone something over $100,000,000 worth of pure copper was prepared for the market, besides the recovery of several millions dollars' worth of silver and gold from the waste. The crude or raw copper is cast into slabs which are made the entering electrode (anode) for a heavy electric current passing through a copper sulphate solution. Pure copper is deposited from the copper sulphate solution on a very thin sheet of pure copper which forms the outgoing electrode (cathode), while the sulphuric acid set free dissolves from the crude copper electrode an amount of metallic copper equivalent to the pure copper deposited upon the cathode. The supply of copper sulphate solution is thus kept constant. By maintaining the conditions within certain limits the current is selective in its action, transporting only the pure copper from the crude slab or ingot over to the other electrode where it appears as chemically pure metal. Similar methods are used for refining other metals such as silver, etc.

Metal Plating.—All electro plating is done by the use of the electric method just described. If we imagine the impure metal anode replaced by a pure metal one, be it of copper, nickel, silver or gold, and the cathode sheet replaced by the object to be electro-plated, we have reproduced a plating bath. Objects of great size such as tubing and conduit pipes are now covered with zinc in this way. Electrotyping is but a variation of the same process.

Metallic Aluminium and Sodium.—Certain molten compounds have the property of conducting the electric current and of breading up at the electrodes just as salts in water solution do. Of special importance in this connection and depending upon this fact is the preparation of the metals sodium, magnesium and aluminium. When a current is passed through molten caustic soda for example this compound is broken up the metallic sodium separating at the cathode and the remainder of the molecule, oxygen and water vapor passing out into the air. The molten sodium is cast into ingots and preserved under petroleum oil. It is of great use to the chemist and is now made at about one-fourth the cost of what it could formerly be produced for by strictly chemical means.

But of much greater importance is the manufacture of aluminium, a metal more abundant than iron, and especially noted for its lightness and silver like appearance. For many years chemists had searched for a cheap method for producing aluminium inasmuch as it is more abundant on the earth's surface than any other metal, and although the price had been reduced from five dollars per pound it could not be made by chemical

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles novel, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

The Coming International Congress of Applied Chemistry

AT the time of the Columbian Exposition at Chicago in 1893, two hundred chemists of various nationalities convened at the invitation of the American Chemical Society and the World's Congress Auxiliary. So successful was this meeting that it was decided to establish a triennial international congress. Accordingly, the following year the first International Congress of Applied Chemistry was held in Brussels. Since that time, at intervals of two and three years, the Congress has convened at Paris, Vienna, Paris, Berlin, Rome and London. The Seventh Congress held in London in 1909 was attended by four thousand one hundred members, 985 papers were presented and the final report of the Congress occupied over four thousand pages in print. The Eighth International Congress is to be held in this country next year, the opening meeting being in Washington, while the Congress proper will hold sessions in New York.

The outcome of these international meetings has been to establish uniform standards and to solve many problems of international importance. At the last Congress thirteen topics were proposed to be reported upon at the next Congress. Some of these questions relate to the unification of methods of food analysis, the unification of terms for reporting analytical results of soils, fertilizers, and ash, the establishment of a central bureau for fermentation organisms, the question of securing greater uniformity in the commercial supplies of potent drugs, the conservation of natural resources, etc.

Probably the report on the international patent question will be of greatest interest because it involves the problem of secrecy versus patents in industrial chemistry. It is hoped that a general discussion of this problem will lead to a closer affiliation of the manufacturer with educational centers. Were the theoretical chemist of the university laboratory permitted to enter the commercial laboratory and plant, incalculable benefits would result. It is so easy in chemical operations to keep a process secret that there has not been much incentive to expose methods under protection of patents. In fact it would be impossible to secure patent protection on some important processes. As a consequence our professors of chemistry find it difficult and well nigh impossible to keep abreast of the times as regards commercial practice. The men they teach are not sufficiently prepared to enter the field of commercial activity by reason of the barriers erected by manufacturers in the path of the instructors of chemistry. It is greatly to be hoped that some way may be found of solving this problem, as it would undoubtedly result in raising this nation to a higher plane in the field of chemical activity. In Germany, for instance, many university professors are employed as consulting experts in large chemical works. Thus they are brought into closer touch with practical applications of chemical principles which accounts in part for Germany's premier position in the field of applied chemistry.

The Eighth Congress will evidently take up matters of interest not only to the chemist but to the general public as well. To stimulate popular interest, four simplified science lectures will be given by representative men of different nationalities.

The committee in charge of the Congress is now concerned with the formulating of rules to govern the proceedings. A set of twenty-two suggested rules has been published, and an invitation is extended to anyone interested in the matter to criticise the rules before the first of December next. These rules apply particularly to those who are to take an active part in the Congress, and relate chiefly to the presentation and publication of papers. In order to avoid the confusion that has existed before, it is specified that papers must be prepared for this Congress exclusively, and must not be read at any previous meeting, or be published in any periodicals before the Congress convenes, and at no time may a paper be published elsewhere without giving credit to the Congress. The papers must be in the hands of the committee before June 30th, 1912, in order to be published and distributed at the meetings. Altogether the arrangements made by the committee seem to be of a very direct and practical nature, which should contribute largely to the success of the Congress.

Our Consular representatives have been active in stimulating interest among chemists abroad, with very gratifying results. A number of affiliated associations expect to meet with the Congress, and hence an unusually large gathering is assured. Aside from the direct benefits to chemists, exceptional commercial advantages should be presented by reason of the fact that many leading representatives of foreign manufacturers will attend. The opportunity should not be ignored of advertising the advantages of New York city as a manufacturing distributing center, and thus encouraging the establishment of branch manufacturing plants in and about this neighborhood.

Dr. Albrecht Kossel

DR. ALBRECHT KOSSEL, professor of physiology at the University of Heidelberg, has arrived in our country, on invitation from Johns Hopkins University, to deliver a course of lectures on "The Chemical Constituents and the Physiological Rôle of Proteids." With the fact that Dr. Kossel received the Nobel Prize in medicine for 1910, most of us reach the limit of our information about this very interesting man, although it would seem that a work deserving of such high distinction in the field of medicine should appeal to a large portion of the lay public.

Professor Kossel's work is much more subtle and more far-reaching than producing a new remedy for some old disease, or devising a painless system for administering drugs. His work has to do with discovering the nature of certain groups of atoms that make living cells do the many wonderful things that are so intimately connected with *living*. And it is because we may well hope that as a result of this work we shall be enabled to control the chemical activities of cells that are not behaving normally, that the specialized study of "proteids" is so important for medicine.

The analysis of the living body as far as the "cell" was completed over seventy years ago. Later the kernel of living matter or "nucleus" was the focus of attention as the seat of the "vital" cell activities, and then this was further dissected with the improvement in the mechanical and the chemical technique of microscopic research, so that certain special organs within the nucleus became the objects of much questioning and speculation among biologists. These are the so-called "chromosomes." So far the scientists had to deal with things that *could be seen*. Beyond that point the microscope could not help, in applying the methods that led from the molecule to the atom and then shattered the atom. Professor Kossel was a pioneer. For many years he has been working on the chemistry of the complex substances that are present in cell-nuclei and that seem to have a close relation to the growth of protoplasm. The "nuclein" isolated from cells by Miescher in 1871, turns out to be a whole series of compounds that are characterized by possessing an albumen base and a nucleic acid radicle. These Kossel identified with the "chromatin substance of the student of cells. On the basis of his work Malfatti and Lilienthal showed why the different cell constituents reacted so differently with anilin dyes, the basic dyes combining with "proteids" in the cell in proportion to the amount of phosphorus present—but the amount of phosphorus meant the amount of nucleic acid.

By very delicate methods of digestion with ferments, acids and alkalies Kossel succeeded in isolating a number of these "nucleins" and even produced one synthetically—not indeed from the "elements," but from such relatively simple compounds that his theory of the constitution of the nucleins is abundantly confirmed. The biological application of his analyses and synthoses is that the nucleins play the leading rôle in the growth of protoplasm inasmuch as the acid portion of the nuclein is capable of combining with itself an indefinite number of albumen molecules, later to split them off again to become a part of the living protoplasm, while the acid portion keeps on assimilating new material. Instead of the chromatin, for example, having a constant composition, the proportion of acid and albumen is constantly changing, according to varying conditions. The work is extremely specialised, but of tremendous importance: it will furnish the raw material for results of great practical importance, as well as of theoretical significance.

The Legend of the Rain-tree

DURING the last few months American newspapers have revived the well-worn tale of the "Peruvian rain-tree," which affords protection against drought. The leaves of this tree are said to have the property of condensing atmospheric moisture in large quantities and precipitating it in the form of rain. According to one writer, "the water falls from the leaves and oozes from the trunk and forms veritable rivers, which can be led as irrigating canals to any point desired. Making liberal allowance for evaporation and infiltration, a square mile grove of the trees would supply for distribution about 100,000 gallons of water daily."

On the strength of similar stories one of the trees to which the name "rain-tree" has been most often applied, viz., *Albizzia* (or *Pithecolobium*) *Saman*, has lately been exploited and sold extensively in Australia. The virtues claimed for it have proved to be altogether illusory, although it is useful as a shade-tree, and is widely planted for this purpose in semi-tropical and tropical countries.

The legend of the "rain-tree" or "raining-tree" dates back to the stories of the Fortunate Isles, where no rain fell from the skies and the soil was refreshed by the moisture shed by a tree of the sort described. The early navigators brought home stories of similar trees in the East Indies, in Guinea, Brazil, etc. The Peruvian rain-tree appears to have been brought to the notice of the world by the reports of a United States consul in Peru, about 1877. These reports were widely quoted at the time, and led the government of India to seek information on the subject from the authorities of Kew Gardens. The investigations of W. T. Thistleton Dyer brought to light a plausible explanation of at least a part of the rain-tree stories.

The traveler Spruce reported his own experiences with the rain-tree as follows:

"The Tamia-caspi, or rain-tree of the eastern Peruvian Andes, is not a myth, but a fact, although not exactly in the way popular rumor has lately presented it. I first witnessed the phenomenon in September, 1855, when residing at Tarapoto. I had gone one morning at daybreak, with two assistants, into the adjacent wooded hills to botanise. A little after seven o'clock we came under a lowish spreading tree, from which with a perfectly clear sky overhead a smart rain was falling. A glance upward showed a multitude of cicadas sucking the juices of the tender young branches and leaves, and squirting forth slender streams of limpid fluid."

This is not the only explanation. That many plants spontaneously exude moisture under suitable conditions is well known. The phenomenon is called "guttation," and has perhaps been most fully described by A. Burgerstein in his work "Die Transpiration der Pflanzen" (Jena, 1904). The moisture drawn up from the roots of plants most frequently passes off into the air in a gaseous form; i. e., by transpiration. If the air is saturated with moisture, and if the supply of moisture to the roots is copious, then liquid drops will be exuded sometimes in large quantities. Molisch records a case in which a single leaf of a species of *Colocasia* gave off 190 drops per minute. Burgerstein gives a list of 241 plants, belonging to 101 families, in which guttation has been observed.

This process goes on chiefly at night, and in cloudy and foggy weather; i.e., when the relative humidity of the air is highest. It is altogether probable that in the moister parts of the tropics there are trees which exhibit this phenomenon in such a degree that the name "rain-tree" may be fittingly applied to them. It is, however, certain that no such process can occur in a dry climate, and that the proposal to plant the rain-tree as a panacea against drought is entirely chimerical.

Artificial Rubber

Another of Nature's Laboratory Secrets Unmasked

By Ira Remsen, President of Johns Hopkins University

ABOUT forty years ago two young chemists announced that they had succeeded in making enough indigo to be pretty sure they had it. The method used by them was entirely independent of the indigo plants. The yield was extremely small and there seemed to be no promise in the method of future commercial success. A quarter of a century later or thereabout the manufacturer was supplying the world with artificial indigo and the occupation of the indigo planter, if not gone, was going. And now the chemical world is all agog over rubber. Last year a specimen of artificial rubber was exhibited at Berlin identical in all its properties with the natural substance. At present there appears, to be sure, to be little prospect of early commercial success along the line suggested, but the results already reached are of such interest as to incite to many efforts to solve the problem.

First a few words concerning rubber. This substance is obtained mainly from South and Central America, though, of late years, owing to the great increase in the demand for it, plantations have been started, especially in Ceylon and the Malay Peninsula and Archipelago, and these are now contributing to the world's supply. In 1909 the production of rubber is stated to have been 70,000 tons. It is obtained from various trees as *Hevea brasiliensis, Manihot Glaziovii, Castilloa elastica, Funtumia elastica, Ficus elastica, Hancornia speciosa*, etc. Deep incisions are made near the base of the tree. The liquid flowing from these incisions is heated to drive off most of the water and the residue is the impure rubber of the market. The valuable constituent is caoutchouc, a colorless, elastic, amorphous substance. This has long been known but little has been learned in regard to its chemical nature until recently.

In general terms it may be stated that chemists do not like to work with gummy substances, but prefer things that crystallize, or that boil without decomposition, or that form definite crystallizable products. Now caoutchouc does not crystallize, it does not boil without decomposition, and until a *few years* ago it was not known to be capable of yielding definite crystallizable products. Great impetus was given to its study by the discovery of Harries that it forms a well-defined product when treated with ozone, and that the ozonide thus obtained decomposes when boiled with water and yields levulinic aldehyde, a substance that can easily be identified.

It has also been shown that caoutchouc forms a so-called nitrosite when treated with nitrous acid, and this nitrosite can also easily be identified. These facts make it possible for the chemist to tell whether he has caoutchouc in hand or not and the scientific study of the substance has been materially advanced in consequence. Before the discovery of these facts a product had been obtained artificially that was described as "like rubber," but the question whether it was identical with caoutchouc or not could not be definitely answered. Now it is possible to determine with certainty whether a substance is or is not caoutchouc.

To identify caoutchouc after you get it is one thing, to determine what it is is quite another. The first step towards the solution of this problem was taken a number of years ago when Greville Williams showed that when rubber is heated to decomposition a very volatile substance is formed which he called "isoprene." This boils at 36 deg. C. and is a hydrocarbon of the formula C_5H_8. Later Harries found that this same hydrocarbon is formed by the action of moderate heat upon oil of turpentine and other terpenes. This isoprene has come to be the chief factor in the artificial preparation of rubber, for it is this substance which when exposed to certain conditions is converted at least partly into caoutchouc.

That isoprene readily undergoes change was observed by Tilden who announced in 1892 that one of the products is caoutchouc. Later he stated that contact with strong acids as, for example, aqueous hydrochloric acid, causes the change of isoprene into caoutchouc, at least to a small extent. Still later he claims to have discovered that isoprene is changed to caoutchouc spontaneously. He says: "Specimens of isoprene were made from several terpenes in the course of my work, and some of them I have preserved. I was surprised a few weeks ago at finding the contents of the bottle containing isoprene from turpentine entirely changed in appearance. In place of a limpid, colorless liquid, the bottle contained a dense syrup in which were floating several large masses of a solid of a yellowish color. Upon examination, this turned out to be India rubber."

Harries tried to repeat Tilden's work, but although he kept at it for seven years he was unable to confirm his results. He says: "Tilden must therefore accidentally have hit upon conditions which caused the polymerization of the isoprene, but, and this is the main point, he did not furnish the proof that he really had produced caoutchouc." Klages had previously publicly stated that it is impossible to produce caoutchouc by the method suggested by Tilden. This was the state of affairs as far as the chemical public was concerned until the summer of 1909. Then Harries received from an English firm a specimen of a substance which it was claimed had been made artificially by a process patented by Dr Heinemann in England. Harries found that the substance was in fact caoutchouc, but he did not believe that it had been made artificially. Heinemann's method consisted in passing acetylene, ethylene, and methyl chloride together through a tube heated to redness. Harries could not make this work and others who tried it also failed.

Up to this time the experiences of Harries had been anything but encouraging. In November, 1909, he received from the Elberfeld Color Factory some specimens of artificial rubber which had been made from isoprene by a secret process devised by Dr Fritz Hofmann. This led Harries to take up his own experiments on the subject again, and toward the end of January, 1910, he was in a position to apply for a patent. The method devised by him consists in heating isoprene with strong acetic acid in a closed tube. The product thus obtained is unquestionably caoutchouc.

From the scientific point of view the problem of the artificial preparation of caoutchouc is thus solved, but it is a far cry from this to commercial success. Given isoprene in sufficient quantity and at a sufficiently low price and the commercial problem will be solved. At present artificial rubber is almost as precious as the diamond, but, on the whole, the problem is in a more hopeful state than the indigo problem was for years after the start was made. The manufacturers and those who are carrying on chemical investigations for them are plainly of the opinion that the work is worth while. That great firm, the Baden Aniline and Soda Factory (generally called the "Badische") has taken out a number of patents in this field, and this is most significant. It is this firm that worked out the indigo problem and is now supplying the world with artificial indigo, having expended in the preliminary work millions of dollars! It is this firm that is placing the manufacture of artificial nitrates upon a firm scientific basis—probably the most important problem before the world as it involves ultimately the food supply. It may safely be predicted that before many years have passed rubber will be artificially prepared in quantity sufficient to supply the great and increasing demand for it. Meantime there is no danger of a famine as plantations are springing up to supplement the supply of wild rubber.

As has been pointed out the first thing to be done is to get enough cheap isoprene. The only way to do this that appears to be in the least promising is to make it from oil of turpentine. The chief constituent of this oil is a terpene of the composition $C_{10}H_{16}$, while isoprene has the composition C_5H_8. The immediate problem, therefore, is to break down the molecule of the terpene, $C_{10}H_{16}$, into simpler molecules of the composition, C_5H_8. If this could be done easily and cheaply the rubber problem would be solved. In this connection it is of interest to note that, according to an article that has just come to hand, Staudinger and Kleven have succeeded in increasing the yield of isoprene obtained from the terpene, dipentene, by heating to a high temperature the vapor of the terpene under diminished pressure. When the pressure is sufficiently low the yield is about 60 per cent. This is a very important observation for the purpose in view. Dipentene itself does not, to be sure, occur in nature in very large quantity, but the chief constituent of American oil of turpentine is pinene, a substance of the same composition as dipentene, and pinene is converted into dipentene by heating it to 250 to 270 deg. C. The way out may therefore be through turpentine. To recapitulate, turpentine contains pinene. Pinene is converted into dipentene by moderate heat. Dipentene when heated to a high temperature under diminished pressure yields isoprene. Isoprene can be converted into caoutchouc by heating it with concentrated acetic acid and by other methods that need not be described here.

There are other hydrocarbons similar to isoprene that undergo changes similar to that by which isoprene is converted into caoutchouc, and there is therefore a prospect of the ultimate preparation of a number of products similar to rubber but differing from it in some respects. The commercial instinct has already led to the patenting of some of the processes involved. This aspect of the subject is, however, or it appears to be, of much less importance than the main problem briefly presented in this article.

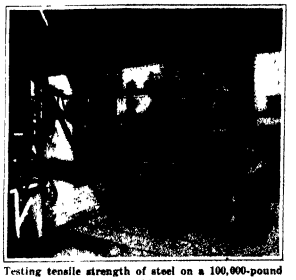
In the chemical laboratories connected with the great factories, especially in Germany, where several hundred well trained chemists are frequently engaged in a single factory, no doubt much work is now in progress which has for its object the solution of the artificial rubber problem. This is also true of laboratories not connected with the factories. From time to time an article will appear in a scientific journal or a patent will be announced giving some result of the work. As usual, of the failures and disappointments which always far outnumber the successes we shall hear very little. But some day we shall wake up to learn that artificial rubber is on the market and then we shall be told truly that scientific research has scored another brilliant success. In the eyes of the world success will mean *commercial* success. But it must not be forgotten that this, if and when attained will be based upon innumerable results that have absolutely no commercial significance. Greville Williams heated rubber and obtained isoprene many years ago. No one dreamed at the time that this simple fact might ultimately become the basis of a great industry. Harries treated caoutchouc with ozone and founded a method for identifying caoutchouc which has proved of fundamental value in all subsequent work on this subject. We want to know what caoutchouc is, whether any one ever devises a method for making it artificially or not and in the highest sense the knowledge will be just as valuable whether such a method results or not. But that is another story.

Arrangement of Laboratory Supplies

By William P. Munger

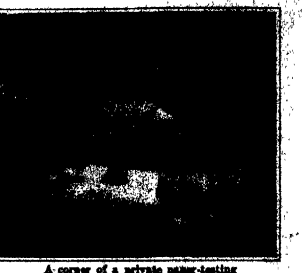
IN an industrial laboratory, containing some 1,500 bottles of chemicals, it is no small job to keep even the chemicals in order. The helpers upon whom the restoration of the bottles to their places devolves usually have little skill and less interest in things chemical. When the chemicals are arranged by the usual alphabetic method, reagents are mostly found, and only then after prolonged search in just the place they ought not to be. Owing to the vast difference in size of bottles, to get any efficiency out of shelf space, it is necessary to have at least two or three alphabets, and when the search is completed through one, the others must be searched.

To overcome these obstacles to speedy work, the following system was recently worked out in one industrial laboratory: The contents were first roughly grouped as to size, and then as to nature of contents. Beginning on the upper and lower shelves, the containers were placed in rows from front to back. The upper left row was numbered 0-9, the second row 10-19, the third row 20-29, etc. The last figure on the front bottle always being 0 and if the shelf did not accommodate 10 bottles from front to rear then the numbers corresponding to the missing bottles were omitted, the next row beginning with the next higher ten. An alphabetical and numerical index was then compiled, giving a little description of the chemical in each bottle (such as C. P. Sticks, commercial powder) and typewritten copies made.



When a given chemical is wanted, a reference to the index is essential, but a glance shows what form it is in, and the bottle of that chemical best suited to the work in hand can be at once selected. Further, if a helper, although it may be his first day in the laboratory, is sent after a reagent and given a number, readily found, instead of an unfamiliar chemical name, the chances are greatly improved of his bringing back what was desired. When the reagents are to be replaced they are much more readily replaced in their correct positions by the method even by skilled workers.

This method is of wide applicability to medium sized stocks of articles, varying in size and use but not in name, such as motor and motor parts construction material, switches, insulators, patterns, etc.



Testing Before Buying

The Economics and Aesthetics of Materials

By Dr. Charles F. McKenna

Testing tensile strength of steel on a 100,000-pound machine.

A corner of a private paper-testing laboratory.

THE simplicity and directness of aim observed in the choice of materials in the old arts and crafts have always elicited the admiration of thoughtful men and the wonder of curious ones. Consider, for example, how animal glue so happily answers the needs of the joiner for uniting two pieces of wood, how easily it can be treated and how perfectly it shows both tenacity and adhesion. This valuable and complex substance was known to the Egyptians, and they are said to have left on record descriptions of how to prepare it of best quality.

As to the metals we can understand that the ancient artificers, once they became acquainted with the different ones, perhaps by accidental smelting, should avail themselves of such obviously valuable aids, thus also of wood and of stone for building materials, but there are many other substances whereof the choice is remarkably discerning and apt, strongly suggesting that it was preceded by much patient investigation and keen observation.

Was it some clay worker making bricks for building who discovered that soft clay might be written upon and then burned as tiles to make imperishable historical records? Who first observed the silk worm and learned how to unwind the cocoon, strengthen the thread and weave cloth from it to make the garments of the rich? The ancients knew how to mat wool fibers together and make felt. They must have understood that the character of the surface of this fiber is unlike that of others and why it makes felting. Those ancient craftsmen evidently possessed a spirit which was eager for research and experiment and which overcame many difficulties of isolation and poverty.

Modern times can point to triumphs of its technologists in the similar search for suitable materials to apply in the arts. But the needs now are broader by the very fact of our greater resources to draw from and our vastly larger fields of activities. It becomes necessary for us to develop a much greater devotion to research into the properties and adaptations of materials. We cannot be contented with our present knowledge. We must have a larger variety of materials than we are yet acquainted with if we are to advance in the arts of construction, transportation, agriculture and manufactures. We need also a better acquaintance with those we have if we are to use them to best advantage and equal the older craftsmen in aptness of choice.

The uncovering of a new product or the application of newly discovered properties of an old one has possibilities for adding to the wealth of nations which can hardly be estimated.

The extraction of oil from cotton seed, an industry which did not exist before the civil war, has now reached a production valued at one hundred million dollars annually.

The virtue that lies in carefully selecting and compounding cement materials before calcining them at a high heat rather than taking them at random and burning at low temperatures has, in twenty years lapse of time, given us the Portland cement industry totaling seventy million dollars annually, and has almost extinguished the natural cement industry which produced not more than a twentieth of this in its best year.

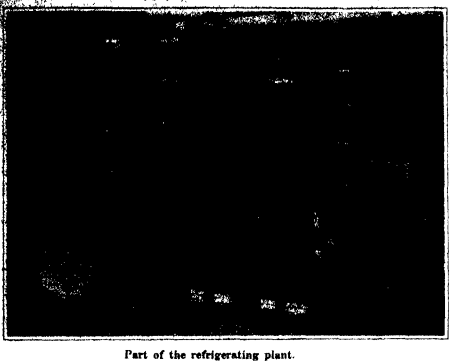
The industry of manufacturing dynamite has grown till more than fifteen million dollars worth are manufactured annually. What will be the corresponding value when this powerful agency has been made safer by the lowering of the freezing point of nitroglycerin and by other stabilizing improvements and shall be introduced into agriculture for the breaking up of subsoil, clearing of forests, and draining of swamps?

Lastly we must exercise a control over all materials we purchase, examining them critically both to determine suitability and to appraise the market value.

Engineering, which now involves so much more than was meant by the term a generation ago, is more concerned than ever over the qualities of materials which are offered to it. In attempting to determine these it finds itself in need of resorting to instrumental means of manifesting differences in properties in order that fallible human judgment may be eliminated as much as possible. The movement began by demands for the preparation and preservation for duplication of the standards of weight and measure. Railway engineering was insistently calling for a deeper study of iron and steel. This resulted in a most intimate investigation of the chemical constitution of steel and brought about at the same time the development of machines and apparatus for observing almost all the physical qualities of materials. Later years have brought us demands of the same nature, not only from the constructional arts but also from every branch of manufacturing. The practice of the art of testing now includes the chemical, physical and mechanical studies of all kinds of iron, steel, copper, alloys, stone, cement, clay, coals, paper, paint, rubber, wood, textiles and a host of materials used in technology.

Determining the heat value of fuel.

The machine on the table was used in testing much of the cement used in the Brooklyn Bridge towers. In the foreground is a portable hydraulic cement-testing machine.



Out of this has grown a larger development of the governmental agencies which were established only as repositories of the standards of measures such as was originally the case with the Conservatoire des Arts et Metiers in Paris. Many nations endowed scientific stations for the applications of precision measurements. The Imperial Physical Technical Institute of Charlottenberg, near Berlin, is one of these, and is the most important and valuable standardizing laboratory in the world. It is composed of two departments, one dealing with the standards of measurement and obtaining correct data as to physical forces, the other dealing with determinations of the accuracy of technical instruments submitted for the purpose and to be absorbed in their turn into use as standards in other laboratories. A staff of more than one hundred experts and assistants is entirely supported by the government for this purpose. United with this is the Royal Material Testing Bureau of Gross Lichterfelde, whose object is to apply results of research directly to technical problems and routine testing of materials. It has the following departments: 1, metal testing; 2, building material testing; 3, paper and textile testing; 4, metallography; 5, general chemistry; 6, oil testing. It employs over two hundred persons and makes many thousand tests annually in these departments. Thus the co-relation of research and technical interpretation can be adjusted nicely under the guidance of the most skilled and patient investigators that the realm affords. France, Austria and England have institutions of like aim.

We are now abreast of the world in this important application of science, for our Bureau of Standards in Washington, founded by Act of Congress of 1901, has been operating for several years under the able direction of Dr. S. W. Stratton, and has made many valuable contributions to the literature of the science of exact measurement. Congress has continued to provide generously for the maintenance and extension of this work. Regarding the value of the chemical departments of the bureau, Dr. Stratton has said: "The relation of the chemical work to that of the other sections of the bureau is exceedingly important. Scarcely a problem can be taken up concerning construction or the properties of materials that does not involve chemical analyses or the co-operation and advice of expert chemists. The entire work of the bureau has been greatly strengthened and its efficiency increased by the organization of the work in chemistry."

A new section has been organized to provide for the routine testing required by the departments in making their purchases of supplies.

Perhaps the most prominent organization under one head availing itself of chemical examination and testing of all its supplies is the Isthmian Canal Commission, since its work constitutes the largest piece of construction and the largest housekeeping proposition that have ever been combined. As this calls for an expenditure of $300,000,000 within a decade, it can be seen that the supplies of materials are an important factor and demand close scrutiny.

These methods are applied by the Commission and the Purchasing Agents' office is concerned over the quality of the bronze wire bought for mosquito screens just as it is over the Portland cement which will be required for the dams and locks. It wants to know the composition and strength of the steel used in constructions, the Babbitt metal used in engine bearings, the dynamite used in blasting, and so on through a thousand things as diverse. This is on the very correct theory that the United States should get full value for everything it purchases, small or large.

Part of the refrigerating plant.

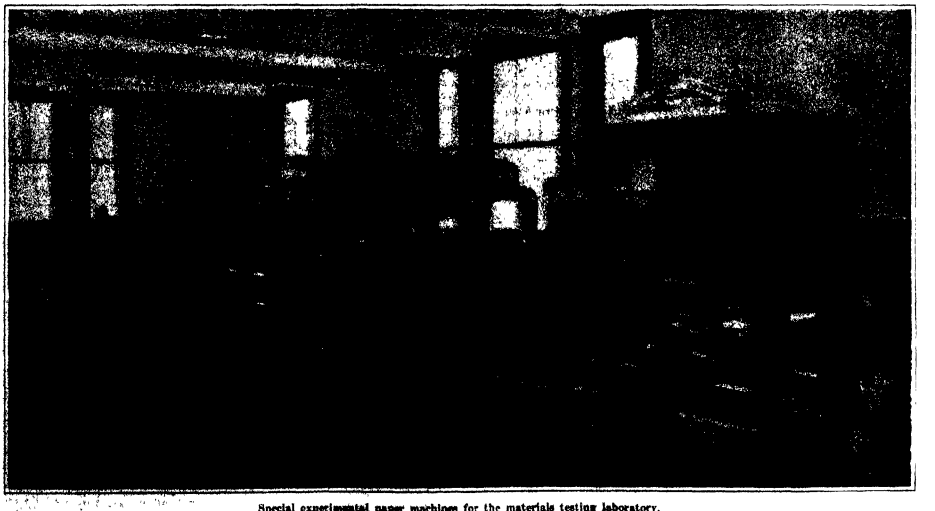
Shop for making and repairing instruments

Besides these government laboratories there are many others in this country which practice chemical and physical testing of materials for determining their qualities and values. Some of the largest of them are operated by the railroad companies, and quite a number by the great manufacturing corporations. In the latter case some concern themselves only with their own product, some with all the materials they purchase, and some have departments adapted solely to research into the properties of materials, applying the results to their factory practice.

In all the large centers of population and manufacturing are to be found laboratories where the needs of commerce for the testing of materials can be met. The same great variety of substances and fabrics are submitted to the chemists and physicists on their staffs, who are frequently appealed to for the decision of important questions. Yet in the application of material testing to the industries one meets at times a marked indifference to its economic advantages. This is the more curious since there are so many cases where they are obvious and so many where successful manufacturers testify to the importance to them of upholding this arm of efficiency.

They know that in many raw materials entering into the manufacture the presence of an adulterant or an inert substance carries a greater penalty than the mere payment for the useless element. The factory and handling charges accumulate against it just as if it was a valuable element and the output of finished material is reduced.

If, for example, one wishes to neutralize acid solutions with lime and employs an impure lime instead of a pure one, he will use more of it and he will be obliged to dispose of more sludge, possibly carrying with it absorbed valuable substances. If one uses a coal whose fuel value measured in heat units, is less than that of a coal used by a competitor he will likely feel the difference, not alone in his coal bills, but in his labor items for stoking and for disposal of refuse.



United States standard of mass—kilogramme.

The manufacture of silk fabrics furnishes another example. One would think that any manager using in large quantities as his chief raw material a substance more costly per pound than coal is per ton would be solicitous to keep exact record of the moisture in the lots he would buy that he might know their absolute dry weight, or "conditioned weight," so called.

Yet in the case of raw silk as used in this country we see something remarkable. 20,387,327 pounds worth $65,424,784, were imported into this country in 1909-1910. Special trains flew across the continent at high speed to bring the Japanese importations from San Francisco to New York city. So valuable was this raw material that a gain in interest and insurance was made by this haste. Yet only 1,298,709 pounds were officially "conditioned" for moisture or examined for other non-silk substances at the silk association's laboratory in New York city during the same period. Of course some silk manufacturers have their own silk conditioning laboratories but they are very few. Moreover these figures are confronted with the statistics of conditioning in Europe where consumption of raw silk is rapidly being approached by that of America. In the Milan conditioning house in

Catalysis

Its Mystery and Its Significance for Life and Industry

By Alfred J. Lotka

CATALYSIS or catalytic action has been somewhat variously defined. To give a rigid definition in simple terms is difficult, or perhaps impossible, and it therefore preferable in an article of this kind to describe the phenomenon, rather than to attempt to define it.

It is for various reasons, advisable to follow Ostwald in grouping together under the general heading of Catalysis two types of action, which perhaps at first sight may not appear very closely related, and which we may speak of as physical and chemical catalysis respectively. The feature which is common to both is that they occur in unstable (technically "metastable") systems. One or two examples will make this plain. By carefully observing certain precautions water may be cooled below 0 deg. C. (32 deg. F.) without solidifying. In this state the system is unstable. Introduce a minute crystal of ice, and immediately a growth of this solid phase spreads out from the crystal "germ" with which the water has been "inoculated." This effect of the ice crystal in bringing about the change from water to ice is an example of what was spoken of above as physical catalysis. Instances of this kind might be multiplied, but one will suffice for our needs. The facts which we want to notice, as being particularly characteristic of this "catalytic" action exerted by the germ introduced are:

1. The amount of water which can be caused to solidify by the introduction of the ice crystal stands in no relation to the size of the crystal. A given small crystal is capable under suitable circumstances, of causing the freezing of an unlimited quantity of water.

2. The result that can be produced by the "germ" is absolutely limited to the establishment of the stabler (frozen) condition, from the less stable (liquid) state. The ice crystal would be quite incapable of producing, under the stated conditions, the opposite change, namely, the melting of the ice. This might be expressed in popular language by saying that what the catalyser does, is merely to help on a change which is "trying" to take place also in its absence.

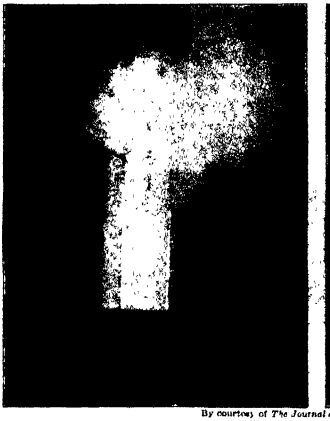
We shall have a few more words to say of physical catalysis further on, but what has been said so far may serve as a basis which will enable us better to appreciate the nature of "chemical" catalysis. It is a matter of very common observation, that a chemical reaction which proceeds with difficulty or (seemingly) not at all on merely bringing together the substances consumed in the transformation, takes place with greater or less ease—sometimes tumultuously—as soon as a small quantity of some suitable material is added. This itself appears to take no part in the transformation, judging from the fact that it can be recovered unchanged from the resulting products of the action. This chemical catalysis, as the effect is called, presents the same peculiarities which we noted above with regard to physical catalysis.

1. A small amount of the catalyzer is capable of causing the chemical transformation of an indefinitely large amount of material (though in practice there is necessarily some loss of the catalyzer through various secondary causes, such as the impossibility of completely separating it from the products).

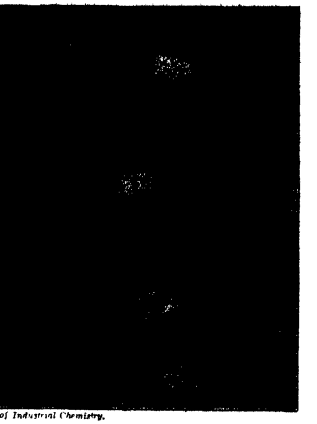
2. The action of the catalyzer is strictly limited to the establishment of a "stabler" condition from a "less stable," or, in other words, a catalyzer can only produce or encourage such a net[1] reaction as brings the reacting system nearer to its equilibrium, and never, under any circumstances, the reverse. In the case of a chemical reaction we may deduce from this second rule a third. For we may state the second rule in this form: "A catalyzer is powerless to alter the equilibrium of a chemical reaction."[2] Since a chemical equilibrium is a condition in which two opposing reactions are going on at the same velocity it follows immediately that:

3. If a catalyzer accelerates one of a pair of equilibrium reactions, it must accelerate the other in exactly the same proportion.

These, then, are the fundamental facts relating to catalysis. It is very natural to ask: "How — by what mechanism — does the catalyzer exert its effect?" To this question we can give at best but a very imperfect answer. We shall do well to be guided in our attempt by keeping constantly before our mind's eye the fundamental facts related above. A mechanical model will best serve to illustrate the nature of the case. We may liken the supercooled water — ready at any instant to freeze on introduction of an ice crystal — or the mixture of $SO_2 + O$ — ready to unite (say at 500 deg. C.) to SO_3 as soon as it comes in contact with finely-divided platinum — to a liquid contained in a bowl at an elevated level. Popularly speaking, the liquid is "trying" to flow to a lower level, and will in fact do so as soon as *a suitable path* is furnished, either by making a hole through the side of the vessel, or by carrying a syphon over the edge of the bowl. Once we have done the small amount of work required to start the flow, we can derive an unlimited amount of energy from the outflowing liquid, since the bowl may have any dimensions whatever without affecting our argument. What prevents the liquid from flowing down from the bowl, is that before it can descend it must ascend, or, in technical terms, in order to pass from a point of higher potential to one of lower, it would have to travel over a path passing through points of still higher potential than the starting point. This would be contrary to the physical laws applicable to the case under consideration.



In the same way we may suppose, that the molecules of SO_2 and O are tending to unite to form molecules of SO_3; all but a small proportion of them however are prevented from so doing by the fact that, in the course of the change, they would have to pass through intermediate states "on the crest of the hill," before they could take their downward path to the more stable condition.



When we come to consider the exact manner in which the catalyzer furnishes this new path, we find ourselves in difficulties. In some cases at least a partial explanation can be given. For example, if the reaction takes place between gases, as in the case $SO_2 + O \rightarrow SO_3$, the action of a finely-divided material, such as spongy platinum, may perhaps be accounted for by the fact that gases tend to form a film of greater concentration near the surface of a solid. Such increased concentration might explain an increased reaction velocity. In other cases it has been shown that in the presence of the catalyzer the reaction takes place in two stages, each stage singly being more rapid than the net reaction in the absence of the catalyzer. But these are at best partial explanations, applicable to isolated instances of a phenomenon which is extremely common, and indeed, probably universal. The cause of the mystery which still enshrouds catalytic action is not far to seek. It is closely connected with the fact that our knowledge of chemical action is almost wholly restricted to the initial and final states. Of the processes which intervene between the instant when a molecule of one compound ceases to exist as such, and the moment when the molecule of the product is completely formed, of these processes we know practically nothing. Referring to this subject, Schönbein[3] has remarked: "Shakespeare says that 'there are more things in heaven and earth than are dreamt of in philosophy.' Thus, presumably, intermediate between the state in which two portions of matter exist after completion of chemical combination, and the state in which they previously existed separately, there is a series of transition states of which the chemistry of to-day knows nothing." With all the advances which chemistry has made since Schönbein wrote these words, they still remain true almost to the letter.[4] So long as we are left in our present ignorance of those states of matter which intervene between the initial and final states in "chemical change," it is very unlikely that we shall be able to form an adequate idea of the nature and inner meaning of catalysis.

So much for the facts and theories of catalysis. Now for its bearing upon technical and vital processes.

From a theoretical point of view it is a somewhat disputed question whether a catalyzer can start a reaction, the German chemist Ostwald holding that it can merely accelerate a reaction, which would go on, however slowly, in its absence also. For practical purposes, this the distinction is of no interest, for a reaction which took thousands of years to become noticeable would be quite worthless and might as well be said not to take place at all. Generally speaking, the function of a catalyzer in technical practice is not only to speed up a reaction, but to render it industrially possible at all. Nevertheless, it may be interesting briefly to consider the economic effect of catalytic *acceleration* upon the process. Suppose that under given conditions one ton of raw material and material in the course of transformation must be locked up in the process, in order to produce a daily output of, say, one ton of the product. With all other conditions unchanged, let us now suppose that by the introduction of a suitable catalyzer the reaction velocities are just doubled. If we require an output of one ton, as before, we can now reduce our plant to the

The current is turned off, and dense acid fumes issue from the apparatus.

On establishing the electric field, there is practically perfect condensation of the fumes.

CONDENSING ACID MIST BY ELECTRICITY

[1] By "net" reaction is here meant the resultant of two opposing reactions, in case we have to deal with a "reversible" reaction.

[2] This does not apply to "stationary states" such as occur in certain light reactions. They are not true equilibria.

[3] *Journal. prakt. Chemie*, volume 38, 1, 199.

[4] We may, perhaps, however hope for new light on these questions from the recent work of Max Trautz.

The Industrial Chemist

What Opportunities for Achievement are Offered Him

By Robert Kennedy Duncan, Professor of Industrial Chemistry at the Universities of Pittsburgh and Kansas

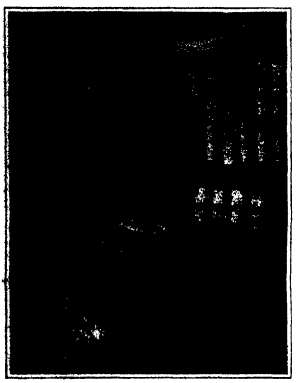
To many men, and the parents of so many men, who are interested in modern science read the SCIENTIFIC AMERICAN that one is tempted to take the opportunity of this special number on Industrial Chemistry for some intimate discussion on the invitation which this science extends. What is Industrial Chemistry, how may one become an industrial chemist, and what opportunities for achievement does it offer? The writer is prompted to this because in his positional capacity he is this year at the receipt of an unprecedented and altogether un-looked-for number of inquiries and personal visits from men and their parents who are just as ignorant of this matter as they are interested. These inquiries arise through the vague, but entirely valid, idea that there are some remarkable contemporary opportunities in Industrial Chemistry.

Leaving for the nonce the nature and scope of these opportunities, let us settle the meaning of the term—What is an industrial chemist? The fact is that "the industrial chemist" and the training he ought to have, is to-day a subject of warm debate among those of us who follow applied chemistry. As is usual in such discussions, the trouble-factor lies in our varying definitions. To one man, an industrial chemist is a chemical engineer, to another, he is a "works chemist," to a third, he is a routine analyst, to a fourth, a scientific researcher, and so on. There are thus many types of industrial chemistry, and many kinds of each type and each kind with its own allure. Industrial Chemists are all alike in this, however, that they are interested in applying chemical knowledge to practical and useful ends. The industrial measure of what is practical and useful is the dollar, and the only material difference between Pure Chemistry and Industrial Chemistry is that with the industrial Chemist the dollar sign inevitably enters into every chemical equation; a subordinate difference is that many industrial chemical reactions are carried out by the ton instead of by the gramme.

How, then, is one to become an industrial chemist? Obviously, by learning Chemistry. An industrial chemist may have some knowledge of engineering, or of biology, or, for that matter, of psychology (all the better if he has), but the *sine qua non* is Chemistry. Chemistry is Chemistry, and since it is *quite* impossible to obtain it self-taught, the novice must enter some institution of learning for the requisite training. It is just at this point that he needs guidance.

If the young man is too old to undergo the school-training that would enable him to matriculate into one of the higher institutions of learning, if he has responsibilities, such as the support of mother and sisters, that would make it inadmissible for him to proceed in his own interest, or if he recognises that he is not so endowed intellectually that he could expect to survive creditably in the severe class-room and laboratory training that university-chemistry infers, then by all means let him enter a trade-school. He could not do better, in fact, than to enter *for* a training the scope and character of which is presented in this number by Prof. Allen Rogers, of Pratt Institute. Nor would he by so doing cut himself off from a genuine success. The industries are in point of fact desperately in need of scientific foremen; i. e., of men educated in chemistry and mechanics to an extent that enables them to co-operate sympathetically and practically with the officials of the company for the elimination of waste and for progressive factory practice; in addition, educated foremen may become superintendents, and superintendents managers, and managers presidents.

But if, on the contrary, the man concerned is interested in chemistry for its own sake, if he eagerly desires to become, genuinely, a scholar in chemistry fully equipped to add to the world's sum of knowledge both pure and applied, and if he has none of the hampering ments stated above, then his course may be as follows:



Before stating this, however, there ought to be said that any man proposing to become an industrial chemist should satisfy himself that when he is ready for work he will be able to qualify under the following demands:

(1) Training (scholarship).
(2) Creative power.
(3) Practical integrity.
(4) Physical health.
(5) Personality; i. e., executive power under the control of common sense.
(6) The ability to govern workmen and to manage foremen.
(7) Personal qualities that would commend him to the officials of the company.

From this list it may easily be imagined that industrial chemistry is no game for old ladies or for little children.

Granted, however, that the man feels that he can fulfil these requisites, he has alternative courses.

He may enter the course in industrial chemistry in any one of the great universities or institutes of technology. In such a course, he will receive, together with a general theoretical and practical survey of the different fields of industrial chemistry, a considerable amount of pure chemistry, some engineering, shop practice, factory law, etc. Such a course in industrial chemistry, admirable in its scope and purpose, is offered by Prof. Whitaker, of Columbia University. The result of such a training is likely to be a man well trained up to his limits, hard-headed, practical and of great ultimate use to the factory which he enters in installing or managing the chemical end of an industrial plant—decidedly, in fact, a man that knows

Robert Kennedy Duncan

what he knows. The danger is that having been trained in *multa*, not *multum*, he may have a wrong conception as to his immediate use in such a factory; and since it is impossible under such conditions to give a comprehensive chemical training in a course of four years, he is likely always to be limited in his power to apply contemporary discovery to practical ends. Still, the industries need, and, indeed, must have men of this very type, and there is now and in the future there will be for them a continuous acceleration of demand. If the man concerned, through his natural qualities, desires to do this kind of thing, this is the kind of thing he desires to do—and there is as much opportunity for him as he could well desire.

The alternative course advises the man to enter the university carefully prepared to forget that he is pursuing to become an industrial chemist, but instead of that, in a comprehensive way, a *chemist*. His course is to take all the chemistry that the curriculum prescribes or permits, and with it what other cognate or cultural study his time affords.

His course will require some four years of undergraduate study followed by two or three years of graduate study. At the end of this time, if he is the young man I take him to be, as a young doctor of philosophy indorsed by his university, he is prepared to take and can obtain an industrial position. He may enter this position without any pretense of knowledge as to the processes involved, but he may take the writer's word for it that, other things being equal, he will speedily surpass competitors who have experienced the other forms of training; he will, in fact, have nothing to limit him in becoming a supreme authority in his chosen field. It may be suggested, that seven years of university training is a long and costly course. As for time, it is worth it; as for cost, in the case of a man for whom alone industrial chemistry would be worth while, it certainly does not require a rich father.

The ideal condition for the right kind of a man to enter the university assumes that his monetary resources do not exceed five cents, in other words, the price of a car-fare to get there. In the University of Kansas, thirty per cent of the students make their way, in whole, through the university, and sixty per cent in part. There is no man to-day worth his salt who cannot, depending solely upon himself, make his way through the university to the appointed end.

After passing through whatever training the man's circumstances or inclinations dictate, he may enter various types of industrial work, in which his training equally with his other qualities will determine whether or not he will stick or advance.

(1) Routine Analysis—Such positions are filled for the most part by young men with but a modicum of chemical training or by chemists who have a particular liking for that type of work. Salaries for men doing routine testing work vary from sixty to one hundred dollars a month, but may yield as high as two hundred and fifty dollars a month. Advancement depends mainly upon qualities that serve to qualify men for executive work. A large number of such positions are open to-day in all parts of the country—in general commercial laboratories, in manufacturing laboratories, pharmaceutical, metallurgical, beet-sugar laboratories, etc., sanitary laboratories, and in various other fields of effort. Such routine positions are particularly valuable for chemists in training, in providing temporary positions by which a supporting income may be obtained for collegiate expenses together with valuable experience.

(2) Government Positions—The Bureau of Chemistry, of Soils, and of Standards, of Mines, the Geological Survey, and various other branches of government constantly employ and are continually looking for skilled young chemists regularly graduated from the universities. While the salary stipends are not as great as the holders of these positions could for the most part obtain in industrial or even in instructional work, the positions themselves are exceedingly advantageous in confirming the training of the universities and in throwing the man into positions in field-work where initiative, self-reliance, fortitude and other manly qualities are developed. The danger related to such positions is that too long continuance in such work is likely to develop the chemist into a bureaucrat, sometimes of rather an offensive type. Chemical positions under government are good stepping-stones to desirable industrial positions. As is the case generally, the demand for good men in such positions far exceeds the supply. Apart from federal positions, all the States require and use many chemists in food, water, fuel, mining, criminal and other work.

(3) Works Chemists and Chemical Engineers—These positions are rapidly on the way to become some of the most attractive in the whole field of industrial chemistry. As a member of the Committee on Employment of the Chemists' Club of New York, it is interesting to watch the character of the applications that continually arise from the various industrial companies seeking chemists. For example, the following positions are open:

Chemist versed in the manufacture of vinegar.

High grade industrial chemist or research engineer; work upon copper, lead and tin alloys; explosives, etc.

Man needed to do work in connection with toilet articles.

Chemist for drug company.

Assistant chemist to manufacture complete line of tablets and pills.

An A No. 1 laboratory man for wholesale drug laboratory.

Man thoroughly trained in laboratory work; a good manufacturer of pharmaceutical products.

Man with practical experience in the U. S. Patent Office work.

Chemist to conduct investigations on the distillation of wood for turpentine.

Two men who have had experience in work on soils, feed and agricultural products.

Chemist and superintendent for sulphuric acid and alum plant.

Assistant chemist for pharmaceutical work.

Man needed experienced in varnishes, japans, and paints. Work of experimental character.

Analytical chemist for powder company.

Assistant organic research chemist of congenial personality; must be thoroughly trained in organic chemistry.

Instructor of junior and senior students practically entirely in chemical technology, engineering training required.

Chemist needed for the manufacture of ordinary pharmaceutical preparations.

Chemist for analytical work of a pharmaceutical laboratory including drug assaying.

For zinc and chemical company, man experienced in the manufacturing of sulphuric acid by the chamber process.

Chemist in oil laboratory.

Assistant chemist, fats, oils, analytical work.

Psychology and Advertising

The Scientific Appeal to Human Nature

By Edward L. Thorndike, Professor of Educational Psychology, Teachers College, Columbia University

PSYCHOLOGY is the science of human nature. Commercial advertising is the art of influencing human nature to buy certain wares. Advertisers are discovering that they need to know the facts which psychology can give about what attracts attention, what sticks in memory, what gives a pleasant impression, what persuades and what leads to a given act, here the act of purchase. Psychologists are learning that the responses of men and women to the illustrations and "copy" of ads are material for the scientific students pure curiosity about the workings of the mind as well as for the economist or expert in business. So a new specialization of applied psychology is fairly started, its birthday being perhaps that of the publication of Prof. Scott's "Psychology of Advertising" in 1903.

No matter which of the many problems that confront advertising practice you choose, you are soon led straight into psychology—often psychology of a very technical sort—if you try to think the problem through to the end. To make known a breakfast food or soap, to connect its name or appearance or both with the fact that it is a breakfast food or soap may seem an easy problem for common sense. Rufton's Soap in big enough type, on enough pages, fences, and cards the method of our childhood—is indeed straightforward and easily done. But common sense does not inform one whether an emblazoning *Rufton's Soap* on an eighth of a page eight times or on a whole page once, on a page alone or on a page with a picture, more surely captures attention and holds memory prisoner. It does not even distinguish between getting the human mind to think of "soap" when it happens to think of "Rufton's" and to think of "Rufton's" when it happens to think of soap. Yet this difference may mean thousands of dollars.

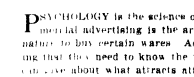

Fig. 1.—A strong claim on attention at small cost

Putting Facts Before the Mind.

Common sense has indeed often made great blunders, neglecting clearness, pleasurableness and habit as causes of attention and over-emphasizing size and repetition, the costliest ways of catching the eye and mind. Even to-day the elementary laws of attention taught to beginners in psychology are not always followed. For example no psychologist among my readers will doubt that Fig. 1 burns in its message, the name of an automobile, better than Fig. 2, and in a fraction of the space.

Fig. 2.—A weak appeal. Too elaborate, vague, and confused.

But the problem of putting a fact, or, more commonly, two facts in connection into a mind, leads soon to far more subtle and technical matters. I choose only one for illustration—the laws of the action of the eye, which is the first enemy for an advertisement to win over. The eye, in getting its impression of a page, a wall, or a billboard, acts roughly as would a small camera in getting a series of pictures which pasted together, would make a picture of the total page, wall or billboard. That is, the eye does not see clearly much at one time nor move in a continuous

Fig. 3.—Too big type is a common error. An unnecessarily hard task for the eye.

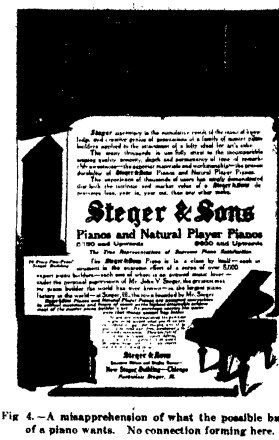

Fig. 4.—A misapprehension of what the possible buyer of a piano wants. No connection forming here.

sweep to cover the object. It turns, stops for one to three tenths of a second, takes in an "eyeful," turns ahead or back, stops as before, takes in another "eyeful," and so on.

Getting an Eyeful of Advertising.

Means have been found to photograph the movements of the eyes in reading a page, examining a picture and the like, and measurements have been made of just how much the eye and understanding do take in during one stop—one exposure of the camera. The reader who is conscious only of looking at an advertising page in a magazine for two seconds and getting a view of it as a whole, really takes a dozen or so different "looks." The eye itself can not see the whole page at all clearly in one look or fixation. The eye sends up a piece-meal report which has to be *put* together. The task of the eye in glancing over a page is a complex task which may be done well or ill, easily or with a feeling of strain.

The advertiser should, of course, other things being equal, (1) make the labor of the eye as slight as possible, (2) furnish any material that the eye is to take in at one glance or fixation in the shape of a convenient "eyeful," and (3) arrange the "eyefuls" that are to catch the eye in its series of exposures in such a way that the piecemeal report they give will be most sure to be put together into the impression he desires to leave.

To meet these requirements even the expert advertiser needs special knowledge of the psychology of visual perception. Common errors are to make type *too large*, as in Fig. 3, so that a single fixation fails to give any whole phrase or word, or to so crowd and muddle printed matter that the eye moves about the page at random. Less commonly the eye is actually tempted *away* from the essential facts in the display.

To get attention to an advertisement is only a first step in a long pursuit of the mind, which must be at last forced by the laws of its own nature to write for and read a catalogue, to examine an article, or, most commonly of all, to buy it.

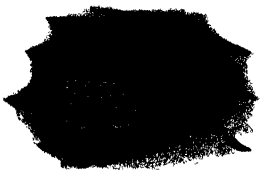
Fig. 5A.

Intuitive Knowledge Supplemented by Psychology.

Experienced advertisers who have studied the results of many advertising campaigns get an intuitive appreciation of how men and women will be influenced by this, that and the other quality in an advertisement. Can such intuitions be usefully supplemented by the psychologist's knowledge of the laws of attention, perception, memory, suggestion, habit, inference and the like?

Let us ask, as a sample case, whether advertisers have anything to learn from one of the simplest of all psychological laws, a law of habit or connection formation, which states that a human being will, other things being equal, make to any situation that response which has gone with that situation most frequently, and with the most resulting satisfaction. Man thinks or feels or does what he has thought or felt or acted in like case with success. Will it profit an advertiser to think of the possible buyer as a mechanism that, whatever else it does, tends unreasoningly to keep together ideas that have come together?

This law leads to five obvious principles for controlling a person's mental connections.



1. Know what his situation is.
2. Know what response you wish to get from him.
3. Know what satisfies or annoys him.
4. *Make* the connection, do not expect the response to *come as a miracle.*
5. Other things being equal, make no connections which you will later have to unmake.

That these principles, which should be the A, B, C of any art of influencing human nature, are not thoroughly known to advertisers, is clear from the following facts. Advertisements almost exclusively to arrest the attention of a casual observer (e. g., advertisements consisting of an interesting but largely irrelevant picture with a mere note of the article and firm name) are used for articles like seeds, doorknobs, nursery stock, or coffins. This is wasteful since possible buyers of such wares would in a great majority of cases make a deliberate examination of advertisements of them, the situation including much interest on their part and a definite intention of comparing merits. Advertisers who use expensive attention-arresting display for such articles *do not consider what the possible buyer's situation is.* Looking casually at a picture of a bon ami cake, he is not in the least likely to think of buying bon ami. He is not in the situation of wanting bon ami. He is not in the situation of wanting anything. He is not in the situation of wanting to buy anything. He is not in the situation of wanting to buy anything that he has not already decided to buy. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again. He is not in the situation of wanting to buy anything that he has not already decided to buy and has not already bought and has not already used and has not already liked and has not already recommended and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used again and has not already liked again and has not already recommended again and has not already bought again and has not already used

daily over a magazine, looking to find where to buy a given article, and looking to find out which is the best article, are three radically different situations that obviously demand different treatment.

Getting the Right Kind of a Response.

Some advertisements are fitted to produce the response "readiness or desire to buy *a* motorboat, *a* piano, *a* greenhouse" as much as or more than the response "readiness or desire to buy *the Jones* motorboat, *the Smith* piano or *the Brown* greenhouse." The

The Easy-Made Dessert.

From the homely materials pictured here are produced desserts so beautiful and delicious that they appear to be the work of the fairies.

All that is required to make a Jell-O dessert is a package of

JELL-O

and a pint of boiling water. Dissolve the contents of the package in the boiling water. As soon as it is cold your dessert is made.

Just now, when the supply of canned fruit has given out, and it is too early for fresh fruit, the delicious fruit flavors of Jell-O fill their places and afford desserts that are especially seasonable and delightful.

The flavors are: Strawberry, Raspberry, Lemon, Orange, Cherry, Peach, Chocolate.

At all grocers', 10 cents a package.

Who shall do perfect manner glove use. Unconditional Promise Book, "Concerning the Well Woman," free.

THE GENESEE PURE FOOD CO., Le Roy, N. Y., and Bridgeburg, Can.

The Birthday Party.

Nan is six years old. Mamma and Bobbie are giving her a party. And what a dinner Mamma has prepared! Just now she is serving a Jell-O course, and there is no mistaking the children's approval. They all like

JELL-O

because it is delicious and beautiful. It is so pure, wholesome and nutritious that kids better for them than any other kind of dessert.

A Jell-O dessert can be made in a minute. Simply add boiling water and let cool.

Seven delicious flavors: Strawberry, Lemon, Orange, Raspberry, Peach, Cherry and Chocolate.

All grocers sell Jell-O, 10 cents a package.

Who Interesting new Jell-O Recipe Book, "Desserts of the World," illustrated in two colors and gold, sent for name of two grocers who sell Jell-O.

THE GENESEE PURE FOOD CO., Le Roy, N. Y., and Bridgeburg, Can.

Fig. 7. Samples from a series of advertisements that are in the main in accordance with psychological principles.

response which any competitor equally desires is confused with the response which the advertiser himself should seek. Certain features of many advertisements of automobiles, Portland cement, bathroom fittings and office furniture make this error. In some such cases a real profit-sharing of supposed competitors may be the reason, but even in such a case it is wasteful to encourage a response as beneficial to future competitors in the same trade as to the advertiser.

Neglect of the third rule, "Know what satisfies or annoys the prospective buyer in the case in question," is very common. Does not Fig. 4, for example, show a misapprehension of what the possible buyer of a piano wants? The pictures of the factories and office building seem psychologically fitted to appeal to a man to place a mortgage or perhaps invest in the company's stock, but not to appeal to the desires and aversions of a music-lover in respect to a piano. Are the pictures of the man and the hall-mat borders likely to connect the idea of a pure rich tone and of beautiful music with that particular piano? Would not the general make-up—the arrangement of cuts and type—positively irritate anyone of an artistic temperament?

The fourth rule—to make connections, not expect them to come of themselves—seems at first thought childish. But did the "Sunny Jim" "ads" connect a given breakfast food inevitably with ideas of delicacy, health and vigor, a diffuse the very name of that food with a charm for appetite, and bind to the sight of its package a strong impulsion toward purchase?

On the contrary, I venture to predict that many of my readers who remember Sunny Jim do not even remember what breakfast food was supposed to have made him sunny; and that many others have, as a result of the "ads," the hardly more valuable connection of thinking of the food in question as the subject of a vigorous advertising campaign, in connection with pictures and jingles about a rather ridiculous looking little old gentleman.

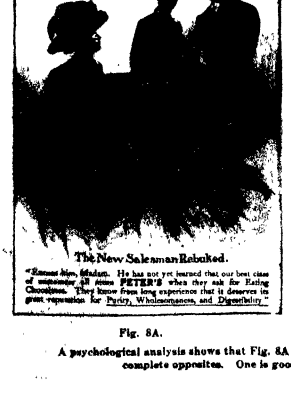
Making the Connection.

As a matter of fact, the greatest amount of psychological ingenuity is demanded to "make the connection," simple though it sounds. To connect the article and the name, to connect each *desirable* quality with the name, to connect that name with the ideas of purchase and possession—each may be a most intricate task, involving, like a problem in chess, the interpolations of dozens of factors. Disturb one adjective, focus one preparatory advertisement ineffective, overdo compliments in the picture, and the whole attack may fail.

I have willfully chosen samples of inadequacy from the best modern advertising practice, in order to make the point that violation of the psychological laws of closeness, relevance and concreteness are perilous to even the most expert writer of advertisements. For perfectly clear cases one may take those given by Prof. Scott of the picture of a breakfast food carton with vermin crawling over it, and of the underwear company which received many orders as a result of a second company's advertisement, the second company's "copy" having been so placed as to connect more readily with the first company's name and address than with its own.

The last warning, against making connections only to have to break them later, should protect any advertiser from many risks. For example, the emblem, slogan or means of attracting attention to the "copy" should not risk boring or disgusting readers in the long run for the sake of an exciting appeal for the time being. A history of advertising would, I am sure, prove that the grotesque the merely strange and the fantastic have been thus dangerous.

A psychologist would prefer not to risk his fortunes on the habits formed by repeated impressions of

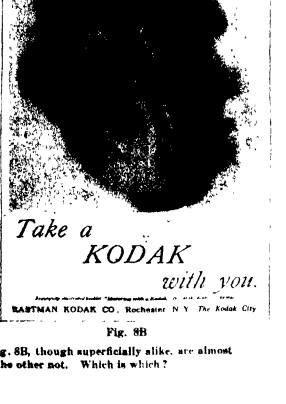


Come Packt furniture.
U All-No after-dinner mint
Slide Well collars.
Breathe-rite braces
Corn Dodger shoes
Holeproof hosiery.
Pre-Shrunk garments.

Yet these are all modern devices used to gain the trade of critical people.

The psychologist expects Fig. 5B to outlive Fig. 5A as a catch-sign, and predicts that even the charming chicken of Fig. 6, that "hasn't scratched yet," may in the long run bore the public and have to give up his place to the safer picture of the soap itself.

I have so far illustrated the value of knowledge of one sample law of human nature—a law of habit—by showing the bad effects of its neglect. On the positive side, I should claim that many of the excellencies of Fig. 7 could have been planned and can be accounted for by the psychological principles of association or connection forming.



Finally, I have chosen two "ads," Fig. 8A and 8B, which superficially seem much alike but one of which I regard as very good and the other as very bad on purely psychological grounds. Let the reader decide which is which and why!

The New Salesman Rebuked.

"Remember him, Madam. He has not yet learned that our best class of customers all desire PETER'S when they ask for Eating Chocolates. They know from long experience that it deserves its great reputation for Purity, Wholesomeness, and Digestibility."

Fig. 8A.

KODAK
with you.

EASTMAN KODAK CO., Rochester N.Y. *The Kodak City*

Fig. 8B

A psychological analysis shows that Fig. 8A and Fig. 8B, though superficially alike, are almost complete opposites. One is good and the other not. Which is which?

Yeast as a Food

THE brewers of Germany produce annually over 70,000 tons of yeast, which is for the most part wasted. For several months there have been going on systematic experiments under the direction of Prof. Delbrück, of the Berlin Institute for Fermentation Industries, for the purpose of finding some practical means for utilizing this product. Special attention has been directed to the problem of its possible availability as human food.

There are a number of commercial preparations on the market which consist essentially of dried yeast, these combine the qualities necessary to adapt them to use as food, having an agreeable taste and odor and a chemical composition comparing favorably with other high protein foods. When properly prepared, dry yeast keeps indefinitely without danger of deterioration, and its high protein content would make it one of the cheapest foods. The slightly bitter taste characteristic of fresh yeast can be readily removed by treatment in the cold before drying, with a solution of sodium carbonate.

Messrs. Voetz and Baudrexel, of the Institute, have determined its adaptability to the nutrition of man and other animals. The chemical composition of the dried yeast, as compared with average samples of beef is given in the following table:

	Dry Yeast	Beef
Water	6.9%	72.5%
Protein	53.4%	21.0%
Calories per lb (approximate)	2,000	607

From the above it is seen that the protein value of the yeast is about two and a half times that of meat, and that the fuel value of the former is over three times that of meat.

Experiments made in feeding dogs showed that 87.2 per cent of the nitrogen in the yeast is assimilated. Large quantities of this material were used on the dogs without producing any symptoms of inconvenience or disorder. Among the animals were some females suckling their young, these seemed to thrive very well under the conditions of the experiment.

A number of the employees of the Institute replaced a portion of the meat in their diets with dry yeast powder using 2/3 ounce with each breakfast for several weeks. No unfavorable results were produced.

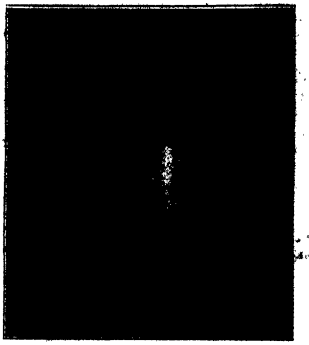
How Electricity Is Aiding the Chemist

(Continued from page 253.)

methods for less than one dollar per pound. In 1889 Mr. C. M. Hall discovered and perfected his electrolytic method by means of which aluminium can now be sold at less than twenty-five cents per pound. The oxide of aluminium, a cheap raw material, though insoluble in most solvents and infusible at ordinary temperatures dissolves in molten alkaline fluorides like sugar dissolves in water. From this molten solution the metal is separated by the passage of an electric current, and appears at one electrode while the oxygen is set free at the other. The use of aluminium where light weight and strength are desired as in automobile and aeroplane construction is well appreciated, and to its cheap production much of the success in these industries depends.

Heat From Electricity.—Although heat derived from electricity is very many times more expensive than heat obtained by the burning of ordinary fuels, there are two conditions which make electrically generated heat of great service to industrial chemistry. These are:

1. Heat generated within the zone of chemical reaction.



2. Heat generated at a temperature higher than that attainable by burning fuel.

1.—In the great majority of chemical reactions, owing to the necessity of carrying away the waste gases produced by combustion, the heat thus generated must be conducted through a containing wall to the material undergoing chemical action. Not only is this in itself wasteful of fuel, but frequently the high temperature necessary on the outside of the container is so destructive of the containing vessel as to render the cost of operation prohibitive. Since when an electric current passes through a conductor of high resistance great heat is generated in the conductor it is only necessary to place this conducter within the container in order to generate the heat at the point where it is needed. The walls of the container can thus be maintained at a much lower temperature than would otherwise be the case, which greatly prolongs their life.

An example of the use of electric heat generated within the reacting vessel is in the manufacture of phosphorus. Although it was known for many years that a mixture of sand, coke and bone-ash when highly heated would produce phosphorus, the reacting mass so soon destroyed the containing vessel as to render the process a failure. By passing a current between carbon electrodes in a firebrick furnace, and feeding the mixture in such a way that the walls of the furnace are constantly protected by some of the unacted upon charge, the process is made continuous and the cost of the material greatly reduced. All of the phosphorus of the great match companies is now made in this way.

Another example of the use of internal electric heating is in the manufacture of carbon-disulphide, a liquid used in large quantities in protecting wheat and other grain from the weevil. This chemical was formerly made by passing sulphur vapor over hot carbon in an iron retort. These retorts lasted so short a time, that the price of carbon-disulphide was never less than twenty-five cents per pound. By heating the carbon to incandescence by an electric current the retort may be replaced by a firebrick furnace of large size and the material made so cheaply that it is now sold for less than four cents per pound.

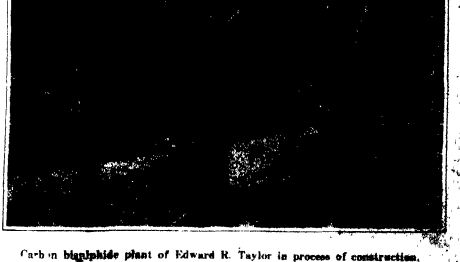
But by far the most important application of internal electric heating is in the manufacturing of steel. The older methods of making steel by the Bessemer and open hearth processes while capable of turning out an immense tonnage are both limited in the extent to which a steel free from dissolved gases, oxides and other undesirable constituents can be produced. The gases of combustion are always present to contaminate the product. When made by the so-called crucible method, in which an amount not over 100 pounds is melted in a graphite crucible, a high grade product is obtained, but the cost is necessarily high. By the application of the electric furnace to steel making a gap which has long existed will be filled and a steel better than the open hearth but cheaper than crucible steel will be offered the consumer. There are a number of types of furnaces in operation in both America and Europe, some having a capacity of fifteen tons. Doubtless the most important field for the electric furnace in the steel industry is as a finishing furnace for the Bessemer converter. This method is already in use in the United States and is apparently giving very promising results, combining, as it does, the very cheap preliminary refining in the Bessemer process with the perfect finishing condition of the electric furnace. The great usefulness of the electric furnace in the preparation of a high grade steel at moderate cost is only beginning to be realized.

Courtesy *Metallurgical and Chemical Engineering.*

Tapping a silicon furnace.

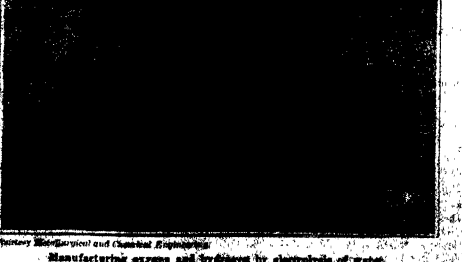
II.—The temperature attainable by the combustion of fuel is naturally limited to the dissociation temperature of the product of combustion; in other words, to the temperature where the carbon and hydrogen of the fuel will no longer combine with the oxygen of the air to generate more heat. This is approximately 2,000 deg. C. In the electric furnace the heat generated by the passage of the electric current is limited only by the amount of electric energy available, and the volatilization point of the material forming the conductor. Carbon does not break up until a temperature of about 3,700 deg. C. is reached, and hence a temperature of this hitherto unthinkable intensity may be realized.

With such an enormous temperature, or even much below this upper limit, many reactions are possible which do not take place at the maximum temperature attainable with fuel, and the working horizon of the chemist is thus greatly widened.



Calcium Carbide.—The great chemist Wöhler some fifty years ago made calcium carbide by melting metallic calcium and carbon, and generated from it the wonderfully brilliant illuminator, acetylene gas. But it was not until the advent of the electric furnace that calcium could be obtained direct from its ore, and then and calcium carbide produced in large quantities. It is made very simply by heating to a very high temperature a mixture of lime and coke, or other form of carbon. The product is tapped in the molten condition from the furnace much as is the case with cast iron. The magic of the electric furnace has transformed the dull and slow burning coke into a compound which with water yields a gas brim full of energy and capable of giving a light of the greatest brilliancy. A new use is developing for calcium carbide in the fixation of atmospheric nitrogen. The plant world might paraphrase the lament of the shipwrecked mariner and say "Millions of tons of nitrogen and not one pound to use." Although the air is 80 per cent nitrogen, it is not in a form available for plant growth. It has been found that when this nitrogen gas is passed over moderately heated calcium carbide, a union takes place, and a compound of calcium carbon and nitrogen called calcium cyanamide is formed. Under certain conditions this compound is a nitrogenous fertilizer and can be used instead of other forms of fixed nitrogen as a food for growing crops. A large plant for the manufacture of cyanamide has lately been finished at Niagara Falls, Canada.

Carborundum.—A second carbide, but one entirely different in its properties is known as carborundum. This is made by uniting silicon and carbon at a high temperature, and forms an exceedingly hard mass which is used as an abrasive, much as emery is used. A mixture of sand (oxide of silicon) and coke is placed around a resistor of carbon and highly heated. After the furnace has cooled a mass of beautiful crystals, brilliant in color and exceedingly hard, is found concentric with the carbon. This mass is pulverized and worked up into abrasive objects of all kinds and is known and used the world over. Again the magic of this intense heat has produced from common sand and coke, a mass of brilliantly beautiful crystals; a splendid butterfly from the common grub.



Graphite.—If in making carborundum the temperature is carried too high, instead of masses of the carbide of silicon there is found only the carbon constituent; but this is now in the form of graphite. This observation gave Mr. Acheson, the inventor of carborundum, a clue which when followed out produced what is universally known as Acheson graphite. Before this discovery we were dependent upon the graphite scales obtained from Ceylon and Siberia, which had to be laboriously worked up into the finished article. Now the article, whether it be a crucible, electrode or what not, is formed of coke and pitch, and when baked is intensely heated in an electric furnace when it is converted into the purest graphite. This method of forming graphite electrodes has been an inestimable boon to the entire electro-chemical profession and has been an important factor in the progress of the art.

Silicon.—Instead of reducing the silicon from sand (oxide of silicon) and then combining it with carbon to form carborundum, it has been found possible to so conduct the operation that the metal silicon is formed in large quantities. A few years ago the element was a curiosity, now it is made and marketed by the ton.

Space forbids extending the list of applications of electricity to chemical industry, but enough has been written to demonstrate the marvelous development which has taken place in the last fifteen or twenty years. What the future holds for the enterprising investigator, no one can foretell.

Manufacturing oxygen and hydrogen by electrolysis of water.

SOME EXAMPLES OF THE COMMERCIAL APPLICATION OF ELECTRICITY TO CHEMISTRY

The Technically Trained Foreman

Educating Men to Co-operate with Expert Chemists

By Allen Rogers, Ph.D., Pratt Institute

A CHEMIST for one of the large varnish factories near New York city had worked out a formula for what appeared to him to be a very high grade product. He turned the formula over to the varnish maker with the request that he make up a batch in as practicable way. The varnish was made, but when tested failed absolutely to give the anticipated results. On making an investigation it was found that resin had been intentionally substituted for the fossil gum that was designated in the formula.

In a tannery where a pack of skins was being treated by a new process of betting, the foreman turned in steam so as to convert the stock into gelatine, and then claimed that the process had dissolved the skin.

Many other instances of this sort could be cited, showing on the part of foremen a disposition to hamper the work of a chemist. It is safe to say that three out of five foremen to-day will do all in their power to make an experiment go wrong. While even men in higher positions will often disparage the chemist's efforts and take the advice of a so-called practical man. To be sure the chemist is often wrong, but usually for the reason that he has been given no opportunity to become familiar with the actual working conditions. The real reason for the lack of co-operation between chemists and foremen lies in the fact that the average foreman or superintendent, being very jealous of what he knows, is afraid that some one higher up will discredit his ability, while at the same time he may fear that the chemist will get his job. On the other hand, the chemist is often to blame as he approaches the man with an "I know everything" attitude, which from the start antagonizes the one with whom he should be on friendly terms.

It is the object of the present article to show what is being done to improve industrial conditions by giving the foreman a technical training. This has involved a radical departure from the usual method of chemical instruction. The writer humbly begs your indulgence for going into detail when referring to this work which is so close to his heart.

In September, 1906, the Pratt Institute inaugurated a new course, known as Applied Chemistry, at which time the writer was appointed to take charge of the Industrial Chemistry. He was directed to equip his laboratory and arrange his course so as to give the student a training along such lines as would have a practical bearing upon manufacturing operations, and would fit the students to become foremen, superintendents and heads of departments in our numerous chemical industries.

As no other schools were giving such a course it became a matter of originality, to work out the details of which was no small undertaking. To meet the demand of a large number of young men who could not afford the time or money for a four year course with college requirements, the course was made but two years in length, and only such subjects included as had a direct relation to manufacturing operations. To afford the necessary practical instruction, five miniature factories were installed, consisting of Chemical Works, Soap Works, Dye Works, Paint and Color Works and a Tannery.

In opening the year's work one man is assigned foreman of the Chemical Plant and is given four of his associates as assistants. Here the preparation of chemicals is carried out on a fairly large scale, the students become familiar with the handling of steam jacketed kettles, vacuum pans, suction pumps, vacuum filters, filter presses, centrifugal pot driers, and drying ovens. It is not only the idea of showing how certain chemicals are made, but the broader question of operating typical apparatus which is of the most importance. The foreman ship system is of value as it gives the student experience in handling men and assuming responsibility. All orders also are given directly to the foreman who in turn must transmit them to his men and must see that they carry out each operation with accuracy and dispatch. It is part of his duties, likewise, to see that his men are kept busy, that his factory is kept clean, that his machinery is in perfect condition and that all products manufactured should be made at a profit. The student assigned as oiler each week also reports to the foreman for instruction. As one group of men finishes the assignment by the chemical works another takes its place and so the work continues.

Those men of the class not employed in the industrial laboratory are engaged on analytical problems in the technical laboratory where they are required to make a complete analysis of such substances as water, gas, coal, cement, soap, oils, pigments, paints, tanning materials and other commercial products. It is the belief of the writer that the analysis of such materials not only familiarizes the student with common analytical problems, but at the same time gives him experience in quantitative separations which will apply to unknown substances more readily than if he had been given abstract analytical problems to solve, and further as these are some of the common substances encountered in the works laboratory he is prepared from the start to undertake such analyses. It is not the object of this course, however, to turn out analytical chemists and this training simply supplements the more important industrial instruction.

When the first group of students has remained in the technical laboratory for two weeks it is assigned to the industrial laboratory again, but this time to the Soap Factory. In this factory not only are various kinds of soaps prepared, with the corresponding instructions regarding the value of the fats employed and the theory of saponification explained, but the student becomes familiar with the apparatus and machinery used in this industry. In this plant he is given more confidence in himself than in the chemical works, for the product which he makes must be of the highest quality to escape the criticism of his classmates and what is still more important, it must be good enough to sell. During the past year 4,000 pounds of toilet soap were made in this model soap factory, all of which found a ready market. The equipment of the soap factory consists of an eighty gallon lye tank, five hundred pound kettle, one hundred pound crutcher, frames, slabber, cutting machine, chipper, soap mill, plodder and press.

Next in order comes the Paint and Color Works, the equipment for which consists of color tanks, filter press, ball mill, kneading machine, change-can mixer, iron mill, two water-cooled 20 inch buhr stone mills and liquid mixer. During the past year over 400 gallons of ready mixed paints were made by the students at work in this factory all of which was sold and gave entire satisfaction. Besides the regular work a large number of white paints were made for the American Society for Testing Materials which will be tested out on fences erected in Washington for the purpose.

In the model Tannery the group is next assigned. Various processes of vegetable and mineral tannages are carried out together with all of the operation involved from the raw material to the finished product. The equipment for this factory consists of a leach house, soak pits, lime pits, suspender pits, liver pits, paddles, mills, fleshing machine, shaving machine, unhairing, splitting, setting out table,

MINIATURE FACTORIES WHERE FOREMANSHIP IS TAUGHT

The International Motor Boat [illegible] of 1911

America Retains the Harmsworth [illegible]

WHEN last year, the fleet hydroplane "Pioneer" of the Duke of Westminster all but won the Harmsworth Cup and showed a speed of forty miles an hour, American motor boat enthusiasts awakened to the development of the hydroplane. It was apparent that a displacement boat like the "Dixie III" would not stand a chance against a hydroplane, provided the latter had no mishap. As a consequence, a syndicate composed of H. H. Melville and Frederick K. Burnham, the Commodore and Vice-Commodore of the Motor Boat Club of America, and Mr. August Heckscher, a member, commissioned Clinton H. Crane to design a hydroplane capable of defending the cup. Mr. Crane, the designer of the other "Dixies," designed a single-step hydroplane, and equipped his craft with two 250 horse-power 8-cylinder V-type Crane motors driving twin screws. This new boat, the "Dixie IV.," is said to have made a speed of 45 knots for several miles. Our photograph shows her at her highest possible speed during a private trial before the race.

In order to win the trophy this year, it was decided that the vanquishing boat must lead in two out of three races. The first of these races was run on Labor Day, September 4th, under perfect weather conditions. The British team consisted of the "Maple-Leaf III.," a speedy English hydroplane fitted with two 12-cylinder motors of 375 horse-power each, which is claimed to have made 49⅝ knots over a mile course on the Solent, the "Pioneer," another hydroplane designed by an American, Mr. Wm. H. Fauber, and fitted with a 12-cylinder Wolseley-Siddeley engine of 380 horse-power, and the "Tyreless III.," a displacement boat fitted with two Brooke engines of 120-horse-power each set in tandem.

The American team, headed by the "Dixie IV.," also contained the "Disturber II." and the "Viva," both of which were chosen at the eleventh hour. The latter is a displacement boat fitted with four 8-cylinder 100-horse power Emerson two-cycle motors arranged in pairs in tandem, while the "Disturber I." is a Fauber hydroplane, owned by James E. Pugh, of the Chicago Yacht Club. She is 31 feet 10 inches in length and is equipped with two 8-cylinder Stirling motors of 140 horse-power each.

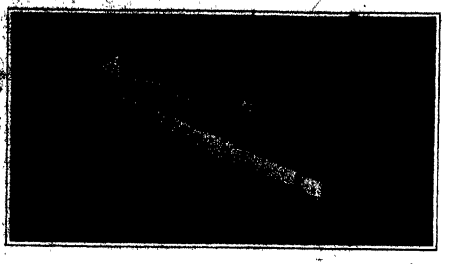
As usual, the 1911 race was held in Huntington Bay over a triangular course of 7½ nautical miles. Four rounds of this course were required, making a total of 30 nautical miles. The start of the race is shown in the photograph which heads this article. The "Dixie IV." led from the start, but was closely pursued by the "Pioneer." The powerful "Maple-Leaf III." broke her steering gear near the end of the second round, and was towed to her anchorage. The "Tyreless III." also gave out after covering 18 nautical miles, and she, too, was towed in. As neither of these boats was disabled so that they could not proceed under their own power, they were both disqualified, and in the second race the "Dixie" had only the "Pioneer" to vanquish. Throughout the first race on Labor Day, the "Dixie" maintained her lead, and finally crossed the line 59 seconds before the English boat, and more than half a mile in advance. The time of the "Dixie" was 51¼ minutes, and that of the "Pioneer" 52 minutes 14 seconds. The "Disturber" finished in 52 42, and the "Viva" in 1 04 12. The average speed of the winner was 35 12 knots or 40 58 statute miles an hour. The "Pioneer" averaged 34 42 knots, or 39.62 miles an hour. As the "Dixie IV." made 39 86 knots, or 45 83 miles an hour, in the elimination race five days previous, it is apparent that she is much the faster boat. It was not found necessary to let her out in the first race, and even less so in the second. The "Disturber II." averaged 32 31 knots and the "Viva" 27 97.

In the second race on September 5th, the "Pioneer" was slightly ahead of the "Dixie" at the start, but the latter overhauled and passed her on the second leg of the course and at the end of the first round was four seconds in the lead. A heavy wooden packing box in the wake of the "Pioneer" was hit by the "Disturber II." damaging her severely. Her owner beached her before she filled sufficiently to sink. Soon after the start of the second round the British boat was obliged to stop owing to engine trouble, and during the 19 minutes she was at rest the "Dixie" lapped her and continued steadily to the finish. The "Pioneer" got under way again and was apparently good for second place, but again the unexpected happened. Her propeller shaft broke while on the last leg of the final round, and within sight of the finish. Consequently the laurels went to the "Dixie," which was a minute and 32 seconds longer in covering the 30 nautical miles than on the previous day, averaging 33 40 knots, and to the "Viva," which averaged 23 06, or 27.5 statute miles an hour.

For the first time, in the race this year, America made an excellent showing both as to speed and reliability. All three of our boats finished the first race, and but one dropped out of the second, owing to an unfortunate accident and to no fault of the machinery or hull.

While the Duke of Westminster did not see fit to increase the power plant of the "Pioneer," and even was willing to wager $100,000 that she would win, the men who built the cup defender doubled her power plant and installed two 8-cylinder V-type four-cycle motors of 250 horse-power each. The motors have a bore and stroke of 7¼ inches, and make a maximum speed of 950 revolutions per minute, although, in the race, they ran at only about 800 revolutions per minute. The "Dixie IV." has twin screws, one propeller shaft being directly coupled to the forward motor, while the other is driven by spur gears from the rearmost motor. This was made necessary on account of the steep inclination of the boat and propeller shaft when under way. A novel feature of the "Dixie IV." is the attaching of a metal step beneath the hull directly under the forward engine. This arrangement makes it possible to build as staunch a hull as is obtained with any displacement boat, and the action of the single step is certainly very satisfactory. The "Pioneer," it will be remembered, has multiple steps according to the Fauber patent. In all there are five of these steps constructed in the bottom of her hull.

The fact that none of the American boats gave out on account of engine trouble speaks well for American motors, which have heretofore not shown up to good advantage in international or other races. The "Viva" was equipped with Emerson standard 8-cylinder, two-cycle motors, and she ran very regularly in both races. This is the first time that a two-cycle motor has been used in an international motor boat race. Despite the fact that the "Viva" is a hydroplane equipped with four 100 horse-power, extremely light weight, two-cycle motors, she did not at any time develop a speed of much more than 30 miles an hour, although her regularity was very good. The "Disturber II." was equipped with two standard four-cycle motors of the 8-cylinder V-type, and this boat also demonstrated the reliability of the engines besides showing fairly good speed. True to her name, she disturbed the water to a great extent, and made much more fuss than any of the other craft.



Now that America has won the Harmsworth trophy for the third time in succession, it is to be hoped that our motor boat enthusiasts will keep it here permanently by building other higher-powered and more advanced types of boats for the future annual races.

Halos and Rainbows

THE correspondence columns of the scientific journals are overburdened with letters from persons who have witnessed one or another of the optical phenomena of the atmosphere, and who describe the same in such a way as to give the impression that they have never opened a book on optics. Strange to say these letters frequently come from men who are more or less prominent in the scientific world. One can hardly escape the conviction that a large number—perhaps the majority—of physicists, meteorologists and astronomers have profited little by the researches of Monge, Biot, Bravais, Mascart, Pernter and other students of atmospheric optics.

There is, for example, a particularly beautiful form of halo—the "circumzenithal arc"—which is nearly always described by persons who thus report their experience as if the phenomenon in question was one of which they had never heard, and which they are consequently unable to call by its correct name or bring into relation with other luminous meteors. A description of this kind appeared in *Nature* for May 11th, 1911 (p. 349). The writer, who obviously had not the slightest acquaintance with the terminology of optics, referred to what he had seen as a "rainbow." Strange to say, the editor naively concurred in this ignorant diagnosis, and published the letter under the heading "A Zenith Rainbow;" notwithstanding the fact that, in a note appended to the letter by a well known meteorologist the correct name was applied to the phenomenon.

Several forms of halo are decidedly common, though they often escape the attention of the casual observer. At the Observatory of Montsouris, near Paris, where halos are systematically watched for, the circumzenithal arc was seen on 111 days in ten years, an average of one day in 33.

The Saharan traveler who has occasion to mention a camel does not call it "a large brown quadruped with a hump on its back." He saves times and obviates misunderstandings by saying "camel." On the other hand persons constantly report that they have seen in the sky a luminous appearance of such and such an size and shape along with other particulars that may or may not possess real scientific interest, the gist of which is merely that they have witnessed the tangent-arc of a halo, a sun-pillar, a lunar cross, a parhelion, or some other luminous meteor that ought to be, but is not, perfectly well known to the majority of educated people.

The SCIENTIFIC AMERICAN believes that its readers will welcome the appearance in its columns, in the near future, of a series of illustrated and plainly worded articles on the optical phenomena of the atmosphere.

The "Mouth-organ" Industry

TROSSINGEN, in the Black Forest of Germany, is the center of the foreign harmonica industry, where most of the world's "mouth-organs" of the cheaper grade are made. One factory alone is said to employ several thousand hands, and the number of harmonicas turned out by all the factories there is enormous, amounting to almost a million annually.

Although the United States imports a large number of the cheap German "mouth-organs," the finer grades are made in this country, and these are held to be equal in every way to the more expensive instruments made abroad. The Germans devote some attention to the manufacture of the more costly "mouth-organs," but their principal output is the cheaper grade.

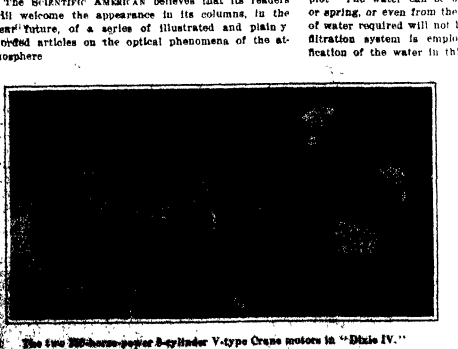
Among the finer grades of harmonicas are the kind known as "concert," which come in sets of from four to a dozen and sell for several dollars apiece. These are tuned in various keys. In one form they show six harmonicas of different keys grouped about a central stem. Many of the elaborate and expensive harmonicas are handsomely decorated with designs of gold and silver upon mahogany. The wood used in the cheaper grades is pine.

Portable Swimming Tanks

A LARGE and permanent swimming tank is a costly affair, especially if it is located in the center of a large city, where ground is valuable. Many German cities are provided with such establishments but many others have been deterred from following the example by the great cost involved, which may be estimated at about $100,000. The swimming bath in Munich cost more than twice this sum. Attempts to provide cheap substitutes for these expensive establishments have hitherto been fruitless. The first practical solution of the problem is exhibited at the International Hygiene Exposition in Dresden this summer and is described in *Hygiene*, the bulletin of the Exposition. This first portable swimming tank was designed by H. Recknagel, a well known engineer of Berlin, and was opened on the 14th of May. The basin for an establishment of this kind can be constructed cheaply of concrete on any plot that is likely to remain vacant for a number of years in a central and accessible part of the city. The cost of a cheap basin of this kind will be covered by the revenues in a comparatively short time, and when the land is required for building, the basin can be rebuilt on another vacant plot. The water can be obtained from a river, lake or spring, or even from the city mains, as the quantity of water required will not be very great if the English filtration system is employed. By continuous purification of the water in this way the number of bacteria per cubic centimeter in the bath can be reduced according to the latest investigations, below the number found in the freshly entering water. A light shed with a canvas roof which will protect the bathers both from the heat of the sun and from cold winds can be cheaply erected over the basin. These movable swimming baths are equipped with locomobiles which will be found useful for various purposes, including the heating of the water and the air in cool weather, thus prolonging the bathing season the operation of the pumps and filters, etc. The locomobile can also be employed for the production of waves by means of the simple Hoeglauer system by which it is possible to produce powerful waves three feet in height. This wave motion not only increases the pleasure of the bath, but presents a sanitary advantage as according to Dr. Brieger, it effects a mechanical destruction of bacteria, it also affords an opportunity for practice in swimming in rough water which is a valuable acquirement.

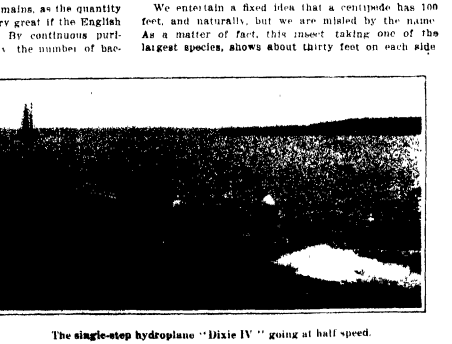
Such a swimming tank, measuring 10 by 130 feet with its shed, etc., can be constructed for about $20,000.

Everyday Misnomers



A VAST number of incorrect notions are acquired by reason of misleading names. For instance, we ask for a Dutch clock. We get the kind we want, so it really doesn't matter that it is not a Dutch clock at all, but one of German manufacture. Practically all the wooden clocks called Dutch are made in the village of Freyburg in the Black Forest. This misnomer is due to simple mispronunciation—"Deutsch" meaning, of course, German.

Nothing is more natural than to assume that India ink comes from India, but it does not, and never did, any more than does India rubber. India ink is a Chinese product, and India rubber comes from South America.



Camel's hair brushes are not made from the hair of camels, but from the hair of the tails of Russian and Siberian squirrels. Camel's hair is, however, employed in the manufacture of certain fabrics to be made into shawls, etc., and it is sometimes mixed with silk.

French briar pipes are not made from the roots of briar, but from the root of a white heath which attains a considerable size in the south of France, where it is sedulously cultivated for pipemaking purposes. The name is derived from the French bruyère the dialect form of which is brière, meaning heath.

We entertain a fixed idea that a centipede has 100 feet, and naturally, but we are misled by the name. As a matter of fact, this insect taking one of the largest species, shows about thirty feet on each side.

The two 300-horse-power 8-cylinder V-type Crane motors in "Dixie IV."

THE WINNING BOATS AND ENGINES IN THE HARMSWORTH CUP RACE

Curiosities of Science and Invention

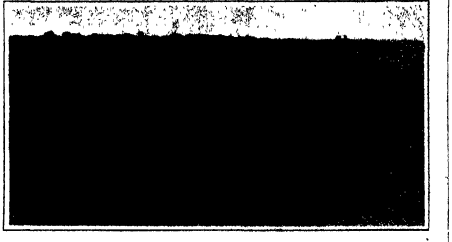
Seventy Automobiles Crossing the English Channel

With recent Prince Henry Race placed navigation before an interesting task, viz: loading on a passenger steamer with in a few hours no less than 70 automobiles and taking these cars with their drivers, their owners and their families, across the Channel to Southampton, where the race was to be continued through England and Scotland.

Most elaborate plans were required to carry out this transport. The number and kinds of cars to be stowed in the various holds of the ship had to be accurately ascertained beforehand so as to avoid any hitch. As the small hatches generally used on passenger steamers were likely to afford difficulty in transferring the automobiles special loading means had to be devised for loading the cars. A platform was built with two iron brackets bent upward at one end. This was suspended from the crane so that it could be adjusted to any inclination thereby reducing the horizontal component sufficiently to provide admission to the hatch. The front wheels of the cars rested against a beam on which sand bags had been arranged for protecting the tires. Adjustable guides at each side protected the cars against any lateral motion. The loading of the cars was effected without any hitch or damage in about six hours, which is the more remarkable as the irregular arrival of the cars resulted in loss of time. The unloading at Southampton also took six hours.

No further difficulty was experienced in stowing the cars in the holds and decks, those located on wooden decks were propped by pieces of timber nailed to the deck, and those standing on iron decks by sand bags slipped in front of the wheels.

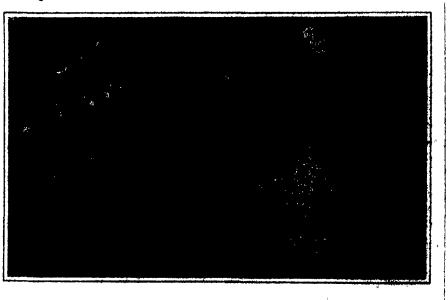
The unloading at Southampton was likewise performed without any hitch and with the exclusive use of the ship's own hoisting devices within six hours. Immediately after the landing of the cars, their gasoline tanks were filled. The cars were then submitted to a thorough cleaning and the race was continued on English soil.



Shipping seventy automobiles.

Tipping a car to enter a hatch.

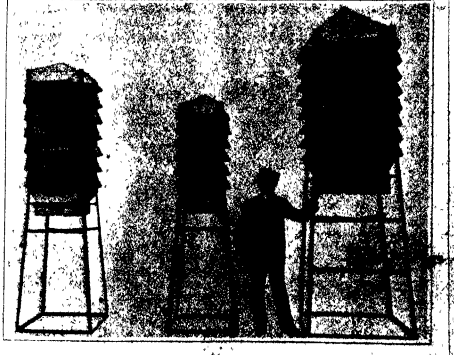
A Stranded School of Whales



On an island off the northwest coast of Tasmania near the entrance to Duck River thirty-seven sperm whales were stranded early this year. How they came to be driven ashore is not known. We can imagine them panic-stricken and stampeding like a herd of bison, but more probably they were driven by hunger and followed a small shoal of fishes, pursuing them into dangerously shallow water at high tide, where they were stranded when the water receded. Whatever the cause, the whales were driven far up on the sands, and being unable to work their way back into water, soon perished. They were discovered by the captain of a ketch who knew that there were whales about by the oiliness of the water and the stench. The stranding of so large a school of whales is decidedly unusual and many excursions to the island have been made by sight seers as well as hunters of whalebone, ambergris and spermaceti. Even the novice will recognize these whales with their enormous blunt heads and narrow toothed jaws as belonging to the sperm or cachalot species.

Thirty-seven whales stranded off Tasmania.

Flower-picking Apparatus



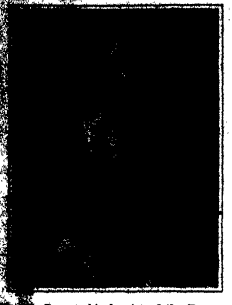
The accompanying illustration shows an apparatus for plucking flowers and collecting seed, which is intended to save a good deal of labor in the garden. The apparatus consists of a tube connected with a pair of shears. At the forward end of the tube is a fork, which is slipped under the flowers. The blossoms imprisoned between the prongs are severed by a blade traveling down the fork and are dropped through the tube into a receptacle at the rear of the apparatus. The device will cut off single flowers very quickly, but also can be used in large. When the flowers are plucked by hand it is almost impossible to break a twig without leaving behind a long sliver of bark. Sometimes even a whole plant must be torn up by the roots. The apparatus can also be employed for collecting seed capsules which are often crushed when picked by hand so that the seed is lost. The entire capsule drops uninjured into the receptacle at the rear, so that the seed is preserved.

An apparatus for picking flowers and seed.

Fighting Moths in Egypt

In order to increase their collections of insects, two entomologists, Messrs. Andres and Maire, of Alexandria, Egypt, tried to improve upon the fermenting liquids commonly used for the purpose of attracting insects. Their experiments proved exceedingly successful, and in 1905 they used them to catch the injurious moths that infest the cotton fields. For their first trials, they employed bands of jute cloth, four inches wide and about sixteen feet long, soaked in the mixture, and hung on posts where the wind would carry the scent over the cotton fields. Moths were attracted by the hundreds, and, by means of chloriform, they were stupefied, so that they dropped into vessels of water. As this method of procedure was not commercially practical, the inventors devised traps in which the insects could be caught. A set of these traps is shown in the accompanying engraving. They are made of bands of galvanized wire gauze placed in a slanting position, with a very narrow opening between the bands to admit the moths. Within these traps the cloth strips are hung. The moths feed on the liquor soaked in the cloth strips, and drop into vessels of kerosene, at the bottom. As many as five thousand moths have been caught in one of these traps in a single night. The success of these experiments has resulted in the use of a great many moth traps, and the catches are counted by thousands, greatly reducing the hand-picking labor. When the traps are used all over the country, it is expected that the pest will disappear from Egypt. The same type of trap is now being tried in France by the wine-growers, who are fighting the moth known as *Cochylis*.

Traps for the moths that infest Egyptian cotton fields.



When the Smoke Nuisance is Punishable

"The man who built his factory some years ago, when architects were in the habit of forgetting to provide the necessary space, and engineers were therefore unable to install boilers adequate for the work to be done, is entitled to some sympathy when he falls into the clutches of the present-day smoke abatement laws—though even in these cases the nuisance can usually be abated at little cost. But the man who to-day, with all its improved knowledge and appliances and practices in sight, erects and operates a smoke-producing heating or power plant should be promptly stopped and punished as the creator of a public nuisance as unnecessary as it is disagreeable and injurious."—*Dr. Holmes.*

Aeroplanes in War.—For the first time in Germany aeroplanes will participate in the army maneuvers to be held near Metz, beginning the 25th inst. Heretofore only dirigibles have participated in the German maneuvers, but the results with these were so poor last year that the Emperor has decided to try aeroplanes.

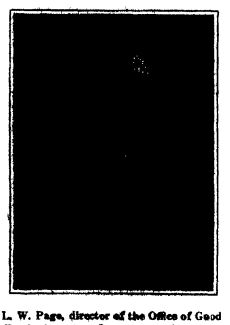
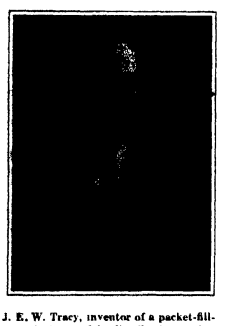
Inventing for the Public



Government Inventors Who Have Given Their Patents Away

By William Atherton Du Puy



THERE is an unwritten law in the government service which stipulates that he who, while drawing a salary from Uncle Sam, makes an invention, shall demand no royalties upon it but shall dedicate it freely to the public. This unwritten law has not always controlled. It was much more often disregarded in the past than in the present. In the history of the government service there are a number of instances of men connected with it who have made inventions from which they have made great fortunes. These instances are, however, growing more infrequent all the time. They were always greatly in the minority. Of the 23 patents that have been issued by the Patent Office to government employees, not a copper cent have been kept from the public. The idea of profiting by his own invention has practically been given over by the government employee and the exercise of his inventive genius is now almost entirely patriotic.

But this need not be true under the law. There is no law which stipulates that the government employee may not profit by his inventions, whether made on government time or in private. Should the government employee inventor see fit to demand the right to his invention there is no law which refuses him whatever profit he may derive from it. Court decisions in general practice take the view that when an employee takes out a patent the subject matter of which is in general line of his employment, there is an implied license of the employer to use the patent. Upon this basis a feeling grew that the government had a right to use the patents of its employees. This idea went still further, upon the theory that the public was the employer, and the practice grew up of giving these inventions freely to the public. The Secretary of Agriculture has gone so far as to issue a general order in which he requires employees making useful inventions to dedicate them to the public.

This view of the matter has been generally accepted in the government service. There are many inventions that might have made their originators wealthy that have been surrendered. There are many others that are merely useful and economical to the government, saving it thousands of dollars a year, which it accepts from employees and for which it recompenses them in no way. The Bureau of Corporations was some time ago asked by Congress for an opinion on the status of the inventor in the government service and the government's claim upon his invention. That report stated that the present attitude of the government tended to discourage invention and held that government service would be improved if inventors were allowed to profit by their patents, being thus encouraged to make inventions along the lines of their work.

L. W. Page, director of the Office of Good Roads, inventor of a waterproof cement.

J. E. W. Tracy, inventor of a packet-filling device used in distributing seeds.

But this is not the present practice. When a man in the government service to-day makes an invention he dedicates the free use of it to the government and to the people of the United States. He has one chance of making money out of it and that is through a sale of foreign rights. Neither practice nor public opinion denies him this. It would seem that there would be little reason why a government employee inventor should take out a patent, if he is not to profit by it after all, but his case is peculiar, as he is usually a scientist, devoting his life to a given line of work and to the service of the public. His invention has something to do with his work and with its effect on the public. He is anxious that the public should profit by his work. If his invention is of any value and he fails to patent it, there is the chance at any time that somebody else may take out the patent and collect royalties from the public. The actual effect of his taking out the patents and giving them to the government and to the public is to prevent some more mercenary individual from collecting royalties. These patents are for the protection of the public rather than for the protection of the patentee.

Among the newest of the patents that appear to be of great importance to the people is that of waterproof cement, for which letters patent have been issued to Logan W. Page, director of the Office of Good Roads, Department of Agriculture. This cement is made by mixing oil with the ordinary cements. The principle also applies to mortars and concretes. It produces a cement that, in the first place, will hold water and may be used for such structures as water tanks. Concretes that are otherwise easily penetrated by water become waterproof. A lining of waterproof cement or concrete will make an otherwise porous structure water tight.

Last May streets were constructed of oil mixed concrete, one in New York city, one in Washington and two bridge surfaces in Ridgewood, N. J. A few months ago a vault 105 feet long by 18 feet wide was constructed of this material in the Treasury Department. The top was a flat reinforced concrete arch and as sufficient tests in bond had not been made ordinary concrete was used to surround the reinforcement. After it had set three inches of a ten per cent oil mixture was placed above. The vault has been perfectly waterproof under very trying conditions. A large water tank so treated in the good road laboratory with a ten per cent oil mixture is absolutely waterproof. Extensive experiments made with oil concrete in basement floors have given excellent results up to the present time. No moisture enters the walls of houses built of this waterproof. Water poured on a basement floor made of it will roll up in globules instead of entering the cement. Col. Goethals is experimenting with it as a material for building locks. It promises to find extensive use in the building trades.

Mr. Page patented his product and two methods of making it. The demand for the material already indicates that there would have been millions in the patents if privately handled.

Dr. Marion Dorset, biochemist of the Bureau of Animal Industry, is a young scientist of great inventive genius. He it was who first found the germ that is responsible for cholera in hogs. This germ is so small that the most powerful microscopes cannot detect it nor can the most delicate filters remove it from water. Dr. Dorset, having isolated the bacterium invented a serum with which to combat it. The serum and the processes of manufacturing it were protected by patents.

Hog cholera was causing a loss of $15,000,000 a year in the United States. When the disease broke out in any locality it went on and on with no power to oppose it. But the serum which Dr. Dorset patented is an absolute antidote. He has repeatedly proven its effect. He has time after time taken a given number of pigs, inoculated half the number and put

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

BUSINESS OPPORTUNITIES

YOUR VACUUM CLEANER should command the Middle West general sale power unit $6.75 to $15 F. P. per set. $5.00 quantities. Andis Sales, Eastern Avenue and 32nd Sts., Beloit, Wis. On main river and railways; many thousands horsepower already developed; further possibilities write Industry, Bureau of Information, Tulsa, Oklahoma.

WANT MAN WITH MONEY to invest in water power plants. Gold, Silver Copper and Lead mining. Mining is a paying business. For further information address Box 66, Boise Idaho.

MANUFACTURING OPPORTUNITY.—The Waltham Building Association is in a position to erect a modern manufacturing building on line of B. & M. Railroad with proper financial backing who is desirous of locating in a growing city. Apply to Waltham Building Assn. Hollis E. Denton, Treasurer, Waltham, Mass.

GOOD BUSINESS OPPORTUNITY.—Owner of well established business, manufacturing and selling a specialty readily sold into general and home trade, desires to interest business man who can be expanded individually. No special manufacturing experience necessary, since present trained assistant help can be retained. This is an exceptional opportunity for any young man, who can command $10,000. Address "Pennsylvania," Box 775, New York.

FOR SALE OR ON ROYALTY.—Street car ticket holder. Strong, simple and thoroughly effective. Cost less than a cent each. For further particulars address Stokstad, Harper Wash.

DEAFNESS.

THE DEAF HEAR INSTANTLY with the Acousticon. For personal use, or to interest others. Booklet describes. You only hear before you purchase. Booklet free. (Imperial Acoustic Co. 202 Beaubien St., Jamaica, N.Y. City. Paris branch 6 Rue d Hanovre.

PATENTS FOR SALE.

ARTIFICIAL RAIN.—New system of irrigation combined with electrified water. Best and cheapest fertilizer. Patented. Unlike anything else. Will work on any quality basis. 2 Olsson, 32 W 9th St., N Y City.

FOR SALE. Patent for a perfect toy balloon. Something new. Very interesting. Will sell entire or part interest or adults. For further information address Balloon, Box 775, New York.

UNITED STATES PATENT FOR SALE. No 1091 071. Automatic Mail Order Carrier. For further information address John Gronick, 1531 Buttner Street, Philadelphia, Pa.

FOR SALE.

SALESMAN MAKING SMALL TOWNS, just what you want for a pocket sideline. Something new snappy and catchy. Write for sample case offer. Specialty Covered. R. Dahne Sales Mgr. 308 Sigel St., Chicago, Ill.

REAL ESTATE.

CALIFORNIA LAND, planted and operated by experts is a splendid investment. Black has best of all crops. Write Geraldinton Farms, Newcastle, California. (Packers Geraldinton Place).

WANTED.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to look after our repeat business after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to work. Pleasant business. No soliciting or canvassing. This is an exceptional opportunity for a man with limited capital to enter a paying business without capital and become independent for life. Write for particulars. Full explanation sent free by H. Marion Price, The National Co-operative Realty Company, L 703 Marden Building, Washington, D. C.

MISCELLANEOUS.

"I AM THE SCIENTIST OF MY MISTAKES."—Astounding theories. Solid opposite Kepler's theory of vortex motion. Matter does not build together as Part 2 read, but of universal opposites, as set forth in fact. No "periodic" energy. Only one ultimate element, another. Momentum underlies all matter, basis of all energies, and phenomena, not time, from energy measure. An Amazing Calculation. Part 3 of Mistakes. Universe call based upon sets of basic orbital vortex motion of all her cents earth and heavens. Astounding theory. Pamphlet, ten cents (coin). C. C. Bates, Pascola, Ill.

PROVE IN 5 DAYS by our PHOTO-FIX. Magazine. Send us your name and $1 and we will send you this magazine absolutely free. Before you invest a dollar any where—get this magazine for 5 days. Then if it is not to any man who intends to invest 5 or more per month. Tells you how! Tells you where to get it—how to judge different classes of investments the Real Earning Power of your money. The magazine six months free if you write today. H. L. Barber Publisher 425 S. W. Jackson Blvd. Chicago.

MAKE BIG MONEY operating a Davidark Post Card Machine. Photos postal cards made and delivered on the spot in ten minutes in the busy street. No darkroom. Invests $175 does not require an experienced photographer to make first class pictures. Pays a large profit of 500 per cent. Write today for free sample and catalogue. Davidark Specialty Co. Dept. V, St. Louis.

MOTORCYCLES CHEAP.—Send to-day for free catalog of new and used motorcycles. Also motorcycle accessories and attachable motor outfits for converting bicycles into motorcycles. Shaw Manufacturing Company, Dept. 24 Galesburg, Kans.

them all in a pen with infected pigs. All of those not inoculated always die and not one that has been treated is affected. It is one of the most absolute antitoxins known to science.

When hog cholera now breaks out in a given locality, all the animals thereabout are inoculated. The outbreak soon wears out for lack of material upon which to feed. An application of the cure with a moderate degree of efficiency results in the saving to the nation of $15,000,000 a year, and this amount would reach considerable proportions in even the span of one man's life.

Dr. Dorset is also the inventor of a secret ink used by the government in stamping meats which have been passed upon by the government inspectors at the packing houses. There was formerly in use in marking these meats a tag that was patented by a private firm. These tags were costing the government about $60,000 a year and were not nearly as effective as the ink which puts the stamp into the meat itself. Dr. Dorset's ink is not patented. The secret of its manufacture can be more effectually kept through not patenting it. The method of applying it to the meat and the devices used in the process, however, are covered by a government patent and in this way the process is doubly protected.

Despite the invention of a hog cholera serum, which saves the people $15,000,000 a year, and the ink which saves the department $60,000 a year direct, this young scientist receives but $3,500 as an annual stipend. He is the sort of man, however, who is more interested in his work than in money, and is entirely satisfied.

J. W. T. Duvel is the government's specialist on grain standardization. It was in connection with this work that he found there was a variation in the weight of grain from five per cent to twenty-five per cent, due to the amount of moisture it contained. Obviously this moisture content should be reckoned in selling grain. Dr. Duvel invented a moisture tester that is now in use in most of the elevators of the nation but from which he has never received a cent in royalties.

The scheme for ascertaining the amount of moisture a given sample of grain may contain is based upon the possibility, under certain conditions, of boiling it off and then condensing it. A given sample of grain is carefully weighed. Then it is placed in oil that has a boiling point a great deal higher than that of water. It is heated to a temperature where the water in the grain goes off in vapor. This vapor is recondensed and carefully weighed. Its weight in proportion to the grain from which it came is the percentage of moisture in the given grain. With Dr. Duvel's device the test may be made in a very few minutes. The same principle, under another patent, is applied to a test of the amount of water in butter.

Joseph L. Harley, an employee of the Bureau of Engraving and Printing, is the patentee of a so-called "press register." This device, when attached to a press, records every impression that is made from it. In the Bureau of Engraving and Printing there are five hundred presses that are used in printing the money, and the postage and internal revenue stamps of the government. This registering of the number of impressions that are made from a given press serves as a check and precludes any possibility of printing money or stamps that are not accounted for. It has been in use by the government for many years and Mr. Harley has never received any compensation for it.

C. R. McBlair, an employee of the Supervising Architect's office, is the patentee of a photographic process which is used in duplicating designs made in that office. The Supervising Architect and Mr. McBlair have both signed a statement to the effect that from $5,000 to $8,000 a year is saved the government through the use of this invention. Yet no royalties are paid to the inventor.

Brig. Gen. William Crozier and Brig. Gen. A. R. Buffington, U. S. A., are the patentees of a mounting for the great twelve-inch disappearing guns, commonly in use in the army. So heavy and so complicated are these devices that it costs $45,000 to manufacture one of them. The records of the Chief of Ordnance, however, show that 395 such gun carriages, embodying features covered by this patent, have been used by the government. No royalties, however, have been paid for this use. The letters patent taken out by these army men state that, "We hereby dedicate to the government of the United States the free right to use, to make, and to have made in the United States for its own use, gun mountings embodying this invention." This procedure is somewhat unusual in the army and navy for, in those services there has been a much stronger tendency on the part of inventors to insist upon profiting through their patents.

B. L. Andrus, superintendent of the mail look repair shop of the Post Office Department, is the inventor of a conical pointed grommet which is used extensively in all the registered mail work and in ordinary mail sacks and pouches of the government. Officials of the Post Office Department admit that this invention would have been a bargain had the government bought it outright for $10,000. There are, in the Postal Service, a great many of these smaller inventions which are not applicable to any other use but which are of great value to that service. Many of these have been patented for the protection of the government against the same action on the part of outsiders. The inventors have, however, received no profit from them.

J. E. W. Tracy, of the Bureau of Plant Industry, is the patentee of a device for the automatic filling of all those seed packets which members of Congress frank to constituents throughout the country. The use of this machine makes it possible for the government to secure competitive bids for putting up seeds. The inventors and owners of other practicable machines state that it is worth $1.32 a thousand packets to do this work. This machine enables the government to save at least three cents per thousand on its packets. As approximately 37,000,000 packets are filled annually, the Tracy patent secured a saving of about $37,000 a year to the government. The inventor, however, in no way profits through this saving.

Probably the most complicated machine that has ever been invented by a government employee is one in use at the Coast and Geodetic Survey, and upon which may be automatically figured the time and degree of maximum and minimum tides at any time or place. A very important phase of the work of the Coast and Geodetic Survey is the forecasting of tides and the making of charts recording those forecasts. The computation of the time of high tide or low ebb for a given place is a very complicated process and there are nineteen different elements entering into the calculation. This tide predicting machine takes all those elements into consideration and, with a single operator, automatically gives the answer. To produce the same result with the same degree of accuracy without the use of the machine would require thirty computers, working throughout the year. On a salary basis of $1,000 each, there would be expended each year in hiring these computers, a total of $30,000. William Farrel was an employee of the Coast and Geodetic Survey when, thirty years ago, he devised this complicated machine. He freely gave his invention to the government and never in any way profited from it. Upon this machine the tide forecasts have been calculated since 1883.

Such are a few examples of the hundreds of patents that have been issued to people in the government service and for which they have received no remuneration. That the law does not require their surrender to the government and that they have been none the less voluntarily given over, speaks volumes for the patriotism of the men who are spending their lives in the service of Uncle Sam on a fixed salary.

Notes for Inventors

Harvester Patents.—In a [illegible] rebuttal of the Report, made by the [illegible] A. O. Stanley, Chairman, [illegible] of the House Committee on [illegible] tion of the United States Steel Corporation, Mr. Edgar A. Bancroft, general counsel of the International Harvester Company, conveys some interesting information on the [illegible] ents. "The knotting device [illegible] by Appleby in 1879," according to Mr. Bancroft, "and there has been no material change in the knotting device or in the general type of the self-binder since then. Inasmuch as there are no patents on the essential parts of the self-binder in existence, a fifty million dollar corporation has this year put out 500 binders. The Minnesota State Prison has sold 600 binders and a well-known thresher company has made an experimental binder. . . . The charge that the company furnishes no insentive to improvements in the machines is equally erroneous. On the contrary, it maintains a large and effective staff of inventors, experimenters and inspectors—far larger than ever existed before—at an annual cost of over $[illegible], and it has added many improvements to the machines, and has greatly increased their efficiency and durability."

A Sailor's Invention.—Luke McNamee, of the United States Navy, has secured a patent, No. 1,000,834, for a shock absorber for searchlights. The door of the searchlight is cushioned by means of springs which hold the door out of contact with the body of the searchlight in such manner as to permit the pressure on each side of the door to be equalized and absorb the shocks incident to gun fire.

Another Dedicated Patent.—Logan Waller Page, of the division of good roads of the United States Agricultural Department, has secured and dedicated to the public a patent, No. 1,000,545, for a cement concrete and method of mixing and preparing the same. The method consists in adding to an ordinary cement and water mixture, a quantity of [illegible] volatile mineral oil. The oil is added before the cement begins to set and the quantity of oil used does not exceed twenty-five per cent of the cement.

A New Biscuit.—A biscuit, having an inner mass of starchy and brittle filaments surrounded by a tougher covering of glutinous filaments which have a binding connection in which the ends of the inner filaments are secured, has been patented, No. 1,000,377, to Edward W. Anderson of Washington, D. C.

Death of William D. Sargent.—William D. Sargent, who is said to have associated with Alexander Graham Bell in the telephone matter, died on August 26th, at his summer home in Somerset. The after an illness of several weeks following an automobile trip from his home in Brooklyn. Mr. Sargent was one of the old time telegraphers and a member of the United States Military Telegraph Corps Society and was also well known in the financial circles of New York and Brooklyn.

Destruction of Rats.—An East Africa publication contains a description of a method of destroying rats, followed in Java, in which carbon bisulphide is employed. In carrying out the method a small quantity, usually about half a teaspoonful of the carbon bisulphide is poured into the rat hole and after waiting a few moments to let the liquid evaporate, the mixture of air and vapor is lighted, a small explosion resulting and filling the hole with poisonous gas, killing the rats instantly. Such a process practised openly might be objectionable under some circumstances because of danger from fire resulting from the explosion and a field for invention appears to offer itself to provide some form of fire-proof gun or explosion chamber suitably formed to be inserted in the mouth of the rat hole and adapted to enclose the explosion and discharge the resulting noxious gas into the hole.

The Safe and Sane Way To Keep Blue Prints and Drawings

Explaining how you can file your Blue Prints and Drawings Systematically; Index them for Immediate Reference in the new "Y and E" Vertical Blue Print Cabinet. The Permanent Solution of the "Lost Blue Print" Problem.

YOU know how it is.

If you use drawings, sketches, blue prints, etc., in your work, the "Search Party" illustration below tells a very familiar story

You want a certain drawing or map, we'll say; you saw it in your office just last week. You send a boy for it; he looks and

"The Search Party"

hunts everywhere. You have a customer, or prospect waiting, or perhaps your Chief has asked for the print. Anyway, important affairs hinge on the finding of it

You may go through the whole pile, lose time, temper, and maybe your Chief's respect for your managing ability, or a possible customer

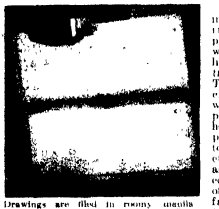
After sweating blood for 20 minutes you may find it And probably it is badly torn, dusty and frazzled Even if it is in good condition, *you couldn't find it when you wanted it*

If drawings are worth keeping they are worth keeping right Why not keep them clean and flat and indexed so you can locate any one in a jiffy"

The Solution

"Y and E" Vertical Blue Print Cabinet No 430 carried in stock Table front when extended can be used as reference shelf or drawing board It is dust proof; drawings are kept flat, clean and smooth; indexed for quick reference.

In the "Y and E" Vertical Blue Print Cabinet, shown here, you can file 700 to 1,000 prints, indexed for instant reference The cabinet is dust proof; takes up but 3¾ sq. ft. of floor space The front is perfectly smooth and may be used as a handy reference table on which to examine contents or make memoranda or corrections



Its History

Two or three years ago D. J Burlingame, of Chicago, designed and patented a special cabinet for filing large prints in the Chicago Association of Commerce. Today we control the rights, and have changed and improved the cabinet until it is the finest on the market. It is truly the proper place for blue prints and drawings See it and you'll agree

Drawings can be removed from the cabinet without extending table front

The Manila Pocket

Drawings are filed in roomy manila pockets suspended from the top Imagine a big vertical file, and these you have it

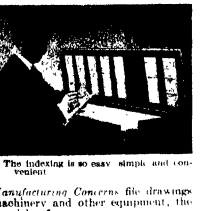
The drawings are filed in manila pockets which are like big vertical folders They are closed half way up so prints are held in place, preventing torn edges, etc Pockets are supported by strips of hard wood fastened at the top Mighty handy.

How to Index

One big advantage of this cabinet is the ease and facility of locating a drawing when filed On the inner side of the cover are eight cards (printed both sides) held in permanent metal racks Cards are ruled for easy writing of index information, and each bears letters, A-B etc In stock cabinets the envelopes are numbered 1 to 20 If you are filing Mr. Brown's drawings in pocket 20, you'd write under B—"Brown—house drawings 20

What Could Be Simpler?

Contractors file blue prints, rough drawings and sketches



Engineers file their big prints and sketches.

Art Stores file prints, valuable sketches; indexby artist's name or subject.

Draft Departments of Manufacturing Concerns file drawings and prints of machinery and other equipment; the cabinet gives it quick reference

Chamber of Commerce—Industrial departments file city maps, sectional plats, etc.

Advertising Departments, Advertising Agents can use this cabinet to file large photos and drawings

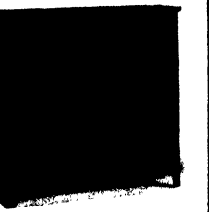
The indexing is so easy simple and convenient

These cabinets are used in many other lines of work. If you have maps, drawings, prints etc., to file you need one, too

What One User Says

Our "Y and E" Vertical Blue Print Cabinet is entirely satisfactory For the purpose of keeping blue prints, maps and other papers free from dust and so indexed that they can be found instantly when needed, we don't believe this cabinet can be surpassed

H R HUMPHREY,
Industrial Commissioner,
The Chicago Association of Commerce



In a Nutshell

1—"Y and E" Vertical Blue Print Cabinet is dust-proof and air-tight

2—Will hold 700-1000 prints

3—Contains 20 strong manila pockets, suspended by two wood pieces at top

4—Prints are filed in pockets and thus kept clean, flat and smooth

Cabinet when closed is dust proof and compact, takes up minimum of floor space

5—All Prints are carefully indexed by name or number, as preferred.

6—Any print quickly findable by referring to index on inside of cover

7—Handiest known way of filing and indexing drawings, tracings, blue prints, sketches, maps, artist proofs etc

8—Widely used by architects, contractors, superintendents engineers and draughtsmen

9—Cabinets are carried in stock in two sizes No. 036 for drawings 40x36 or less, and No. 430 for drawings 44x30 or less—and in quartered and plain oak in "Y" and "E" standard golden finish

10—Cabinets of special sizes and in special finishes furnished to order Estimates on request (Advise drawing size and quantity to be filed)

Complete Booklet Free

For your convenience, we have prepared a handy, pocket size booklet which gives full details and information about this handy cabinet It is yours for the asking Mail the coupon now It is handy for immediate action

There is another Winter coming. Does it mean furnace drudgery, excessive coal bills and a shivery breakfast every cold snap for you?

Don't blame the weather; don't blame the house; don't blame the furnace—it does the best it can. Instead, put in a modern, sanitary, adequate, economical, Pierce Heating Equipment—a steam or hot water system that is a success in over 200,000 homes. Pierce Boilers are built to meet every heating requirement. They save fuel, require little attention, cannot get out of order, and save their cost long before they have served their time.

Your steam-fitter will tell you just what Pierce Boiler your house needs, and the cost.

DON'T BUY A GASOLINE ENGINE

Until You Investigate The Temple Make. Its Great Advantages are 1st—Lowest Fuel Consumption for Itself in Fuel Saving. 2nd—Governs Steadiest Power Stream, adapting it especially for operating farm machinery. 3rd—Easy on the machine it operates. 4th—Uses Gasoline, Kerosene or Gas. 5th—Perfect Lubrication. 6th—Starts Easily and Quickly, occupying minimum space. 7th—It is the King of Portable Engines. No engine has so wide a range of use. You will make a mistake if you do not write for information. We make 1½ to 8 H. P. single cylinder engines. 6 to 20 H. P. two cylinder engines. 30 to 50 H. P. four cylinder engines. All heavy duty, slow speed engines. For surety of operation and low fuel cost our engines lead. Temple Pump Co., Manufacturers. 439 West 15th St., Chicago, U. S. A. This is our 19th year.

Testing Before Buying

(Concluded from page 957.)

1909-1910, 19,885,217 pounds of silk were conditioned, and in the 4 years [illegible] 11,378,962 pounds. The moisture in silk varies with the climate and the morals of the seller. The normal amount is about eleven per cent. A moist situation can increase this three per cent or more. If in all the above stated American importations two per cent of excess moisture was paid for as silk, the loss to the buyers was over one million dollars. It is probable that all the conditioning houses of Europe receive as much as $500,000 for fees for services in thus examining raw silk.

But undoubtedly the largest patronage of the materials laboratories comes from the constructional industries. In these it is now quite generally recognised that the proper control of materials by specification and testing is a species of insurance upon the finished property. Considered thus the cost would be but one or two per cent of the material in place; but this percentage of cost is not charged annually as the fire insurance, but only once, and its beneficial influence endures for the lifetime of the structure. Moreover, a moral and legal value adheres in a work which, during its progress, has the reputation and proofs of being constructed only of carefully examined materials.

Chance of failure from defective material is reduced to a minimum, and if it does occur from other causes the possession of these proofs is invaluable. Not to be despised even by the financier are the æsthetic values.

In our own times architects in congested centers of population would seem to have entered upon an era that is unlike any of the past, and one that has inaugurated a school of its own. Whether this influence will persist, whether it will develop into more noble and ideal forms, more lasting monuments must rest with the technologists who study materials and adapt them for the use of architects, and also with the latter as they learn and utilize the knowledge. If this is not done we shall have early ruin, discouragement, defeat and a return to the more undoubted stability, if not beauty and usefulness, of the stone age of architecture.

Cast iron has been eliminated from our columnar structures, the steel used is carefully examined to insure the best quality, and the covering paints are chosen to secure the best protective value. Stone, tiling and impervious substances are sought for to protect the facades and roofs, but all of these materials have defects which research will conquer if the demand becomes insistent enough to bring the rewards.

When our laboratories of standards and of research founded by the government or by private wealth shall have been in operation a longer time, and the observers more numerous and more skilled, when international comparisons and exchanges of data shall be more frequent and general than now, the progress in these arts will be more rapid and beauty will spring from utility. We shall see these sciences which the æsthete sometimes considers of secondary importance really bringing about a restoration of beauty. This will be not alone by mere adornment and charm of variety caused by a wider choice of form and color, but most importantly by in spiring the pleasure that springs both from an impression of stability and grandeur and from contemplation of a work that harmonizes lightness with stability and fitness with gracefulness. Beauty, in fact, is a result we can long for and justly expect from these studies, not only beauty in architecture, but in the mural and sculptural arts, in textiles and in most products of human skill and handiwork. Then we shall enjoy our surroundings the more, for, as Ruskin has said, beauty has been appointed by the Deity to be one of the elements by which the human soul is continuously sustained.

Catalysis

(Concluded from page 958)

proportion of one to two, and the investment on capital invested in the plant and in the materials locked up in the process is diminished in the same proportion. It

[illegible] of the [illegible] we must [illegible] lytic material locked up in [illegible] which [illegible] amount [illegible] sample of this kind is [illegible] tact process for the manufacture [illegible] phuric acid, which gives [illegible] acid of high concentration [illegible] rather more compact than [illegible] old chamber process, even [illegible] careful purification of the [illegible] in the new process calls for [illegible] sive apparatus.

It would require a special [illegible] do justice to this most fine [illegible] important process, which represents [illegible] of the most striking applications [illegible] catalysis that have occurred in [illegible] chemistry within the last few [illegible] In a brief survey of the general [illegible] catalysis such as this article is [illegible] to present, it is impossible to [illegible] technical details, but one brief digression may be permitted, to bring before [illegible] reader an illustration of a recent [illegible] opment in the technique of the [illegible] process, especially as the principles involved have been discussed in these [illegible] in relation to operations in an entirely different field of applied science. [illegible] contact process, as distinguished from the chamber process, produces anhydrous sulphur trioxide, which is not ordinarily placed upon the market as such, but is converted into sulphuric acid by hydration. To the uninitiated it might appear that this hydration should be the easiest of all operations, inasmuch as it is well known to the first year's student in chemistry that SO3 possesses extreme affinity for water. In practice, however, it is found, that unless special precautions are taken, when the trioxide comes in contact with the absorbing bath, dense white fumes of sulphuric acid mist are formed, which are extremely difficult to condense. The reader may recall that Oliver Lodge's experiments on the precipitation of fogs by means of electric charges. Prof. F. G. Cottrell of the University of California has taken the line of experiment following in the steps of Lodge, with a view to condensing the fumes such as occur in various industrial processes, notably the sulphuric acid contact process. By the courtesy of Professor Cottrell and the editor of the *Journal of Industrial Chemistry*, I am enabled to reproduce here some photographs of the experimental installation for the condensation of sulphuric acid mist. The first picture (page 248) shows the apparatus with the gases from a converter passing through it untreated. The second picture shows the effect produced upon turning on the electric discharge. It will be observed that the precipitation of the acid mist is practically complete.

The mystery which surrounds the true nature of catalysis is not by any means a matter of purely academic interest. Technically it is felt in the fact that there is little or no general systematic method by which we can be guided in the selection of a suitable catalyzer for a given reaction. As the result of this, the discovery of such a body is very largely a matter of accident and good fortune. A rather striking example, which well illustrates this point, is quoted by Erunck in the description which he gives us of the evolution of the industrial process for the synthesis of indigo by the Badische Anilin und Sodafabrik. In the course of this process, which represents one of the most remarkable triumphs of modern industrial chemistry, it is necessary to oxidize naphthalene to phthalic acid. This oxidation at first offered difficulties. One day, however, a batch of the material quite unexpectedly yielded with ease to what appeared to be the usual treatment. The case seemed to baffle explanation, until finally the cause of the phenomenon was discovered in a broken socket, from which a small amount of mercury had escaped, and, mingling with the reacting substances, had produced by catalysis the effect desired, the rapid oxidation of the naphthalene by the sulphuric acid.

We have spoken so far only of organic

The ambition of every tire maker in the world is to make his product as good and as popular as the famous

NOBBY TREAD

Never before in the history of motoring has any type of tire achieved such success. Everywhere, from coast to coast, Nobby Treads are replacing every other form of non-skid tire or non-skid device with a very possible kind of service. And it is because the big, thick, diagonally-placed knobs grip any kind of road, no matter how slippery, and do absolutely prevent skidding or drive-slipping.

Nobby Treads are sold wherever

UNITED STATES TIRES

Continental Hartford
G & J Morgan & Wright

are sold. Four-fifths of the best dealers thruout the country sell them.

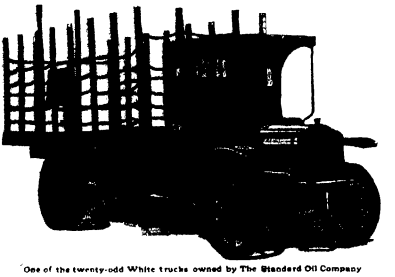
Tires
Third Version
Puncture

Ask the Man Who Uses Them

Are these arrayed with Security Tire Protectors. They are the only materials on our devices Motorcycle or other tire casualties — the only ones we responsible for time-wrecks of motor car service — not responsible for blowouts, rim cuttings, chafed tires, loose treads, tire destroyers always lurking about. This year the Standard Non-Skid is a new tire. It equips the tire with the same process protection, non-skid qualities, wear and tear, added comfort.

Standard Non-Skid Tire Protectors



Security Tire Protectors are made of fabric and rubber, they have almost the same elasticity, wear, tear, strength and flexibility as the tire itself. They are placed between the tire and the tube, where they do their work. They are held in place by the pressure of the air in the tube. They are not fast by any method, but are free to move with the tire. They are made in all sizes for all tires. They are guaranteed for the life of the tire. They are sold by all dealers. Write for booklet.

Standard Tire Protector Company
Cleveland, Ohio

ate by inanimate agencies. Of the greatest importance in technical work and for vital processes are the innumerable cases of organic catalysis, or, as it is commonly termed, fermentation. For certain lower organisms have the power of catalytically bringing about various chemical decompositions. Among such organisms we number some good friends, but also some of our most insidious foes. There are bacteria which act as scavengers, converting noisome waste products not only into inorganic salts, but at the same time into plant food. Others assist certain plants in extracting from the air the inert nitrogen, "fixing" it in a form available to the plant. Bacterial fermentation produces alcohol for beverages and for industrial use. And so on, the list might be prolonged almost indefinitely. Then there are those dread visitors, the disease germs, that come upon us unseen, and, stabbing in the dark, spare neither young nor old. They, too, probably do their work by catalytic action, producing deadly poisons within our body. In the triumph of modern medicine, the keenness of our natural eye has been so far increased by the assistance of the microscope, that we can now discern these diminutive and terrible aggressors. We know something, too, of their chemical means of warfare, and are learning to fight them with their own weapons.

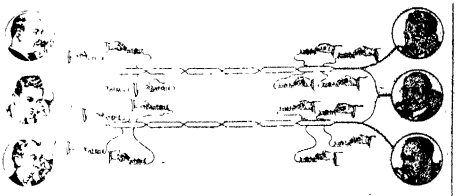
Let us now return for a moment to the case of the crystal "germ," which initiates the formation of the solid from the liquid, for instance in a body of super-cooled water, or in a supersaturated solution of Glauber salt. This case presents a special feature, to which attention has not so far been called. It is the product itself which acts as catalyzer, or, in technical language, the case is one of "auto-catalysis." This particular form of the phenomenon is of peculiar interest owing to its close relation to a fundamental property of living matter. This relation is clearly brought out if we consider side by side a simple case of inorganic auto-catalysis and a typical example of its organic counterpart. On the one hand, then, we have before us say a super-saturated solution of Glauber salt, on the other hand, a vessel containing a sterilized infusion or other material suitable as a culture medium. Each of these two systems is quite stable if left undisturbed, and will retain its character indefinitely under such circumstances. But, introduce a vestige of a Glauber salt crystal into the one, or a minute quantity of a suitable bacterial germ into the other, and immediately a transformation sets in, giving rise in the first to a growth of crystals, and in the second to a growth of living matter. Furthermore, just as the same infusion is capable of producing a variety of different organisms, according to the particular germ with which it has been inoculated so a solution supersaturated with several salts will respond to each specific crystal germ introduced by the growth of the corresponding crystalline substance. In one respect, however, the two cases seem to differ. It is quite impossible, so far as is known to-day, to cause the growth of living matter in a bacterial culture medium except by the introduction of a "germ." Only life can give rise to life, within our knowledge. In the case of the crystal growth, it is often a comparatively easy matter, when no crystal germ is available, nevertheless to start crystallisation, either by increasing the degree of supersaturation of the solution (e. g. by cooling), or in some instances by mechanical agitation or analogous means. The organic chemist, however, knows that there are substances which are very refractory in resisting all attempts to crystallize them. Thus for instance, it is a rather rare occurrence for glycerine to assume the crystallized form even at very low winter temperatures. The distinction pointed out is therefore after all not so fundamental as may at first sight appear. For a more detailed discussion of this very interesting subject of the analogy between crystallization from a supersaturated solution and the origin of life, the reader may be referred to Ostwald's very stimulating series of lectures, published in English under the title of "Natural Philosophy."

For the sake of simplicity, and in or

One of the twenty-odd White trucks owned by The Standard Oil Company

Motor Truck Advantages

THE man or firm that has a better delivery plant has an advantage. It isn't important that it saves money—that it makes a cheaper delivery—although if the right trucks are chosen, under most circumstances, it will be also more economical—but the important thing is, that the superior facilities supplied by motor vehicles gives their owner advantages—it outstrips competition—it serves the customers better. Live business men may no longer dodge the issue—motor trucks are here to stay—it's only a question of who will be first to grasp the opportunity in his line, or his town.



The Advantages of the White Truck

WHEN it comes to buying machines the best machine is cheapest no matter what it costs. Here's where White motor trucks score—everyone has heard about the white gasoline-engine design—how it foreshadowed what is accepted now as the best foreign practice and what is rapidly becoming adopted in this country by the most aggressive manufacturers. Next, each White truck is as well built as the most scientific, modern steel alloys will permit. In addition, every piece of steel is heated-treated to make White trucks as staunch as a truck may be built. The long-stroke engine makes them economical in operation—makes them efficient—the kind you must recognize as having unusual merit. White trucks may be grafted into your delivery plant completely revolutionizing its capacity—giving it vitality without demoralizing your present force. Any bright teamster can drive a White truck, it's so simple.

May we send you a catalogue and testimonials of some of the world's largest users?

The White Company

838 East 79th Street, Cleveland

Double Tracking The Bell Highway

Two of the greatest factors in modern civilization—the telephone and telegraph—now work hand in hand. Heretofore each was a separate and distinct system and transmitted the spoken or written messages of the nation with no little degree of efficiency. Co-operation has greatly increased this efficiency.

The simple diagram above strikingly illustrates one of the mechanical advantages of co-operation. It shows that six persons can now talk over two pairs of wires *at the same time* that eight telegraph operators send eight telegrams *over the same wires* With such joint use of equipment there is economy; without it, waste.

While there is this joint use of trunk line plant by both companies, the telephone and telegraph services are distinct and different. The telephone system furnishes a circuit and lets you do your own talking. It furnishes a highway of communication. The telegraph company, on the other hand, receives your message and then transmits and delivers it without your further attention.

The telegraph excels in carrying the big load of correspondence between distant centers of population; the telephone connects individuals, so that men, women and children can carry on direct conversations.

Already the co-operation of the Western Union and the Bell Systems has resulted in better and more economical public service. Further improvements and economies are expected, until time and distance are annihilated by the universal use of electrical transmission for written or personal communication.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY
AND ASSOCIATED COMPANIES

One Policy *One System* *Universal Service*

der to bring out more clearly the analogy of the crystal "germ," we have chosen for our example a bacterial growth in a simple culture medium. The phenomenon of auto-catalytic growth is, however, of course, quite general in all living matter. Indeed, Wo. Ostwald and T. B. Robertson have shown that the curve representing the rate of growth of various organisms closely resembles in character that calculated for a certain type of inorganic auto-catalytic reaction. Just how much significance is to be attached to this resemblance, is perhaps an open question. Of the general auto-catalytic character of the growth of living matter, however, there can be little doubt

It is impossible in a short review of this kind to do justice to the entire field here broached. Much has been written on catalysis and probably still more remains to be said For a concise resumé, replete with reference to the literature on the subject, the reader can probably not do better than turn to J. W. Mellor's very excellent little volume "Chemical Statics and Dynamics," one of the series of text books of physical chemistry edited by Sir William Ramsay. It is the hope of the writer that enough of the subject has been presented here to give the reader a general idea of the nature of the phenomenon and of its important bearing upon a number of questions of the highest technical and vital interest

The Industrial Chemist.

(Concluded from page 203.)

For analysis of iron and coal, advantageous to know use of calorimeter

For analyses of miscellaneous materials used in manufacturing work position in research laboratory

Man needed who is familiar with heat treatment of steel and metallography of steel

Chemist experienced in analyses of iron and steel and steel products

Young man well acquainted with food and fermentation analyses

For regular analytical work, inclusive of mining precise apparatus work

Chemist to take charge of extensive salt works on the Pacific coast

Chemical engineer to design evaporating distilling and condensing machinery and to superintend its installation

Chemist trained in beet sugar and agricultural chemistry Much original research work Thorough training required

Good chemist strong, of good moral habits, for medicine company

Chemist to do experimental work in developing commercial products

Graduate of some school of accepted standing in chemistry analysis of oils, gums resins, petroleum products pigments coal, and boiler water Research later if man shows ability

Young graduate chemist for analytical work Must be an accurate analyst and able with proper assistance to do both chemical work and physical testing

Laboratory chemist Work will be mainly iron and steel

Man familiar with the manufacturing of paint

Experienced man for experimental work and satisfaction of processes

Assistant analytical chemist food and drug analyses

Several young chemists for routine work on iron and steel analyses

Instructor in mineralogy for university and analyst to department

Energetic chemist with working knowledge of electricity with good initiative and good chemical training

Chemist with knowledge of pharmacy, able to do analytical work

Demonstrating chemist who understands the use of liquid chlorine for bleaching

Several chemical engineers for factory

Bright young man with knowledge of chemistry and bacteriology

Chemist for research laboratory with, preferably, metallurgical training

Chemist with some experience in manufacturing of nitre-cake and sulphate of soda

Experienced sugar house chemist

Chemist for assistant in research laboratory

Assistant chemists in laboratory

Chemist well versed in the nitrating of cotton and the properties of amyl acetate.

Chemist for analytical tests and research work of a physical-chemical nature

Chemist able to keep ordinary accounts and to serve as understudy to the chief chemist.

Competent man needed to take charge of manufacture of tablets salts and hypodermics

Pharmaceutical chemist to take charge of laboratory, able to make fluid extracts, elixir tablets etc

Bacteriologist and analyst in private laboratory, to take charge of routine analyses

Chemist for investigation in making wood spirits of turpentine, well drilled in organic chemistry

Photometric and testing gas analyst.

Chemist for cotton seed products and fertilizers

These applications are for the most part for small men, and even so they do but constitute, probably, one one-thousandth part of the positions that are open to-day for competent men. And, even so, the call has but started to sell.

It may be said, carefully and advisedly,

There's a Carborundum Stone for Every Sharpening Need

For the carpenter, the mechanic, the man-about-the-house, the boy in the manual training school, the housewife in the kitchen—Carborundum means sharper tools and better work.

Perfect Team Work of Perfect Units—that is what Wins the Typewriter Game. The

L. C. Smith & Bros. Typewriter

(Self-Starting, Long-Wearing)

is a rare and unusual combination of mechanical features of superior excellence, each of which is designed,

First—To do its individual work better than it could be done in any other way.

And,

Second—To work so smoothly and accurately, in conjunction with all others, that the completed result is just as perfect as the work of any individual part.

That is what makes a good-working typewriter—it is what justifies the overwhelming verdict of 150,000 users in approval of the L. C. Smith & Bros. Typewriter—it is why this typewriter does all kinds of work superlatively well without attachments and gives no disappointing results.

Send for free illustrative matter today.

that in the immediate future and for twenty years the demand for works chemists will far exceed the supply. The revolution in factory practice that is proceeding is the most amazing in the whole history of American industrial development. The factory of whatever type that does not possess at least one works chemist will be an anomaly.

The larger factory organizations are now rapidly establishing bureaus of research requiring the services of many chemists. It is as the heads, or chiefs, of such bureaus that men have some of the largest opportunities in contemporary industrial chemistry Even to-day salaries of from ten to forty thousand dollars a year are being paid to chiefs of research.

Equally attractive in opportunity is the profession of consulting chemist One of the most significant features of the International Congress of Applied Chemistry that met two years ago in London was the presence there of consulting chemists whose incomes derived from specialized knowledge in practical chemistry were princely The man who can make himself a supreme authority even in a very limited field of industrial chemistry has limitless opportunities for achievement and of adequate reward

Still again, a chemist, neglecting both positional and consultative work, may work simply as an investigator. In the past such a man was almost inevitably robbed To-day as a general rule he receives equitable treatment, particularly if he comes of good scientific antecedents

Finally, as one of the most significant illustrations of the spread of scientific ideas in industry, there should be cited the establishment at the Universities of Pittsburgh and Kansas of the system of Industrial Fellowships The University of Pittsburgh has received some eighty thousand dollars from various companies, the whole amount of which is to be expended in the next two years in salaries for chemist-investigators In the University of Kansas some thirty-five thousand dollars have been involved. All this money passes out of the direct control of the donating companies for chemical investigation

The Technically Trained Foreman

(Concluded from page 255)

making machine, rolling jack, glazing jack, buffing wheels, and measuring machine. Special rooms are also provided for finishing, drying and tacking. As will be noticed the equipment for this line of work is more extensive than the other. The reason for this is, that the National Association of Tanners are cooperating with the Institute in providing more extended courses in this branch of industry, which shows every sign that our manufacturing interests realize the importance of this kind of education

By the middle of the winter term each student has worked in all of the model factories and has finished his instruction in dyeing, so that for the remainder of the year his time is devoted entirely to that industry in which he intends to specialise

Like all new undertakings this course of instruction has been somewhat criticised, especially by those who have not taken the trouble to investigate the methods followed and the object to be attained It has been said that it is nonsense to teach a young man a little about soap, a little about dyeing, a little about paint, and a little about leather. This perhaps would be nonsense if it were all that the course accomplished, but such is not the case. Up to the time that the student begins to specialize it is not so much that he learns about any particular industry, but it is what he learns about operating typical machinery, handling men, assuming responsibility, and gaining self-reliance that counts In other words, he is brought in touch with manufacturing operation, he handles material on a sufficiently large scale to produce something which has a commercial value. If through carelessness or failure to follow directions he spoils a lot of goods it means an actual loss in dollars and cents which in a factory would be very apt to cost him his job. That this method develops self confidence is evident by the pride and interest which each foreman, and his men as well, take in the product manufactured, especially when the product is of fine quality, and it is also

How to Motor Anywhere Without Asking a Question

TODAY a motorist can tour from one end of the United States to the other without asking a question as to route and without losing the road.

It is Simple and Easy—

There are today available a number of route books which give the correct speed indicator mileage at every landmark, railroad or change of direction.

All of these route books which have been adopted as "official" by the Automobile Clubs (and most of the others) have been laid out with the Warner Auto-Meter, "The Aristocrat of Speed Indicators."

Because exhaustive tests proved to the Road Map Makers that **every Warner was just like every other**, and that the mileage shown by the Map Car Warner would appear on the trip dial of *every other Warner* that ever passed that point

Note How Touring With a Warner Works Out in Practice.

We could easily fill this space with touring experiences, all leading up to the same conclusion—hundreds of miles of absolutely unknown territory traveled without a single direction asked, even in the large cities. A couple will suffice.

The first week in June a millionaire manufacturer of Davenport, Iowa, while in Detroit, bought a popular priced car to drive himself " The first time he ever took hold of a steering wheel was on this car, in the outskirts of Detroit His lessons gave him the "bug" to such an extent that he determined to drive home to Davenport. So he bought an Official Route Book and a Warner and made the whole distance without asking a single question.

At Every Direction the Warner and the Route Book Corresponded Exactly.

A few days ago we met a Motor Enthusiast in Chicago en route for San Francisco with his wife and son. He had never been more than a short distance away from New York before. He had not been compelled to ask a direction up to that time—nor will he the remainder of the distance If every owner of a car could have listened to his enthusiastic eulogy of the Warner, they would never again be satisfied with an inferior indicator.

An Exclusive Warner Refinement Which Adds Still Further to the Joys of Touring.

All Warner instruments of the dial type (see illustration) have two resetting buttons for the trip mileage figures. One resets the figures to 000 0 with a single turn The other works on the tenths of a mile only, making it possible to turn up any desired mileage on the trip scale This makes it possible to drive around the boulevards or through the parks at any point and then in a few seconds set the mileage back to correspond with the Route Book readings.

Those who tour regularly will appreciate this refinement

Those Who Select Unreliable Indicators Because of Low Price are Missing the Big Joys of Motoring.

The Warner was selected for surveying the routes in these different Route Books because unvaryingly accurate and reliable **Every Warner was found to indicate exactly the same as every other.** No two indicators of other makes indicated the same.

You should have a Warner on *your car to interpret these routes for* the same reason, *if you do any touring.*

If you don't tour you are missing the most fascinating part of motoring.

WARNER AUTO-METER

gratifying to note the disappointment when the product is not up to the standard, or the cost of production exceeds the price received for the finished article.

When the student begins to specialize, however, a different condition obtains, and he then does learn, not a little, but very much about that particular industry into which he hopes to enter for his life's work It should be plainly understood that no school can turn out experienced paint makers, or expert tanners, but that the training received so fits young men that they can readily adapt themselves to the conditions encountered in the manufacturing plant.

Of the one hundred and two young men who have taken this course there are ninety-nine employed in chemical lines, of which number sixty are doing practical work Of the latter number seventeen are employed in tanneries, sixteen in paint and color works, and the remainder are scattered throughout other lines of industry These men hold positions as Managers, Assistant Managers, Superintendents, Assistant Superintendents, Foremen and helpers.

Although many of the graduates go into analytical lines we do not make this our aim, for we feel that that field belongs to the colleges and technical schools The one great object which is always uppermost and for which we are constantly striving is to train young men for responsible positions in the factory, where by reason of their technical training they will be able to work more intelligently and in sympathy with the chemist, who under present conditions often finds it impossible even to try out his ideas in a practical way owing to the non-receptive attitude taken by those who have the practical work in hand

We are a nation of vast resources and if we wish to conserve them we must improve our factory conditions. Not only must we have the trained chemist with his scientific and technical knowledge, but we must have technically trained and intelligent workmen as well. The foreman who works by rule-of-thumb is no better than a machine, but the man who uses the brains which God gave him and knows what he is doing will not only make a better product, but will be capable of grasping the details of the technical points involved

It is the humble opinion of the writer that the time is fast approaching when all positions of responsibility will be held by men who have received a technical education, either in the university, college, technical school, trade school, or vocational institution, and especially from those schools which aim to emphasize the practical side of the technical subjects they are endeavoring to teach; for then the foreman the superintendent, and the chemist can talk in a language familiar to them all, and the details will no longer be shrouded in mystery

An American Rotating Aviation Motor

THE present Gnôme rotating motor, which is so widely used on flying machines, is not a French invention in principle, as many suppose. In 1898 the first revolving cylinder motor made its appearance in this country, which was afterward embodied in the Adams-Farwell car.

The originators of that pioneer motor of its type have now brought out a 72-horse-power motor which revolves vertically. No carburetor is used. Gasoline is injected into each cylinder by a device which feeds exactly the same mixture to all cylinders. Hence it is possible to do away with the inlet valve and to employ one valve for both inlet and exhaust. Only air is drawn in by the suction stroke of the piston, and the gasoline is sprayed within the cylinder, where it is mixed with the charge of air before compression The single valve in the head of the cylinder can be made amply large to insure a full charge and a free exhaust

In order that the cam which controls the action of all five valves may be relieved from the heavy load of opening a large valve against high pressure at the time the exhaust takes place, the cylinders are provided with auxiliary exhaust ports, which are uncovered by the piston on its inward stroke. No check valves are required for these auxiliary ports. On the suction stroke, pure air,

Mortgage Bonds TO YIELD 6%

Offered at Par and Interest

DENOMINATIONS of $100 — $500 — $1,000

CAREFULLY selected [illegible] Farming real estate in the best districts of New York City, conservatively appraised at $3,000,000, has been pledged to a Trust Company, as Trustee, to secure these bonds.

The management of the Company has had many years of successful experience in this class of real estate.

After all fixed charges are paid, earnings are sufficient to guarantee the interest and sinking fund on the bonds.

Improved New York City real estate is unquestionably in value many times that used, as are the bonds of most of the world, and is the foundation to which all value in land as the United States emphasizes to grow in importance.

New York Real Estate Security Company 6 per cent. Mortgage Bonds are a safe investment.

No one can afford not to investigate this investment.

all over your farm without cost of operation. Rife Hydraulic Ram automatic. Rife Engine Co. 2150 Trinity Bldg. N.Y.

We have been asked

If we use the name of the subscriber when writing to the people whose names appear on the lists sent in by our friends.

Of course we do not mention the name of the person who sent us the list without permission. If this doubt has deterred you from sending us a list don't wait any longer, send in the list at once and rest assured that your wishes regarding the use of your name will be respected.

All you need do

Is simply send us the names of those whom you think the "Scientific American" will interest and we will do the rest. Of course the more names you send us the better will be the results obtained and the longer the period for which your personal subscription will be extended.

For each new subscription received from the list you send us we will extend your subscription four months. Thus if we get three subscriptions from your list we will extend your subscription for a full year.

Don't fail to put your name and address on each list you send us, so that we may be credited to give proper credit.

Mail all lists to Circulation Department, Scientific American, 361 Broadway, New York City.

Every Razor must be stropped

Corns Ended in Two Days

The pain stops instantly. Within two days the whole corn loosens and comes out.

Blue-jay has done this fifty million times. It will do it for you—that we guarantee—no matter how tough the corn.

The secret lies in a bit of B & B wax—a wonderful invention. It loosens the corn without soreness or pain.

You don't feel it at all. The corn is forgotten until it comes out.

Go get it. Don't let corns torment you any more.

A in the picture is the soft B & B wax. It loosens the corn.
B protects the corn, stopping the pain at once.
C wraps around the toe. It is narrowed to be comfortable.
D is rubber adhesive to fasten the plaster on.

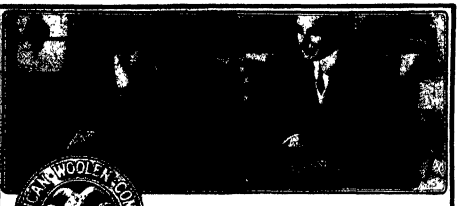
and not a mixture of gas, is drawn in. The air aspired through the auxiliary ports and suction stroke becomes a part of the explosive mixture in the cylinder, and since it is constant in quantity, it does not affect the operation of the motor

The motor is controlled by regulating the amount of gasoline used. The only adjustment that may be construed as belonging to the carbureting system is the valve by which this control is accomplished.

To lubricate the motor, an oiler is employed which consists of a single rotary member, much resembling in form the cylinder of a revolver, with longitudinal chambers bored therein Each of these chambers carries a plunger which, as the cylinder revolves, is driven from end to end by two cams, thereby causing a small amount of oil to be drawn into each of the chambers at the bottom, and ejected into a corresponding tube at the top. An extra heavy grade of cylinder oil is thus supplied to the various bearings and to the cylinders, thereby obviating the necessity of splash lubrication, which in other rotating cylinder motors calls for the flooding with a great quantity of oil, and the consequent gumming of the valves and spoiling of the spark plugs

In order to insure against the accidental stoppage of the motor, two spark plugs are provided for each cylinder, as well as two independent ignition systems.

Instead of circular flanges, longitudinal flanges are employed, as the result of a series of experiments to determine the action of the air in circulating about the cylinders of a rotating motor Since the air is thrown off radially from the cylinder walls, it would seem that the logical arrangement of cooling ribs or flanges is that which has been adopted. There are structural advantages in placing the flanges in this way, for the cylinder is strengthened against tensile strain caused by the action of centrifugal force and the explosions



The material of which the motor is made is vanadium chrome nickel steel The bore is 6 inches and the stroke likewise 6 inches. The rating is 72 horse power by the A. L. A. M. formula (square the bore, multiply by the number of cylinders, and divide by 2½). On actual propeller tests it is claimed that more power than this has been developed Furthermore it is stated that a 9 foot 6-inch propeller, of 6 feet pitch, has been driven at 900 to 1,000 revolutions per minute

The makers state that only one gallon of lubricating oil is used to 20 gallons of gasoline instead of 1 to 4, or 1 to 9, which is found necessary with European motors

Moving Pictures of the Coronation

ACCORDING to a German trade paper devoted to the interests of the moving picture industry, the activities of the moving picture makers to obtain good films of the coronation were equal to the exertions of any of the newspapers to publish the fullest and best accounts of the ceremonies All told, we learn, fourteen firms sent 200 operators to the coronation They were well received and had to pay heavily for good positions, as much as $1,500 in one case It is said that not less than 10,000,000 feet of film were required, which was used up at a rate of about 200,000 feet an hour by each of the cameras

Many of the moving picture theater owners had made arrangements to exhibit the coronation films on the very evening of the coronation itself. Some of the railroads considerately placed special trains at the disposal of the manufacturers, and thus the films reached the provinces with astonishing rapidity The films were developed on board the trains and positives made immediately. On the very night of coronation day films were thrown upon the screens at Liverpool, Manchester, Birmingham and even in Paris The representative of a French firm, who took passage on the "Mauretania," developed his negatives and made his positives on board. Immediately on his arrival in America he distributed his films to the various film exchanges with whom he had made arrangements.

AMERICAN WOOLEN COMPANY OF AMERICA

Oswego Serge—for men's attire depends not on fashion's whims. It is a staple fabric and worn through all seasons.

A serge suit is part of every man's wardrobe. Whether the suit be custom-made or ready-to-wear, the sterling quality of **Oswego Serge** speaks for itself. **Oswego Serge** is made by

American Woolen Company
Wm M Wood, President.

Oswego Serge is made in a deep, rich Navy Blue and in Black.

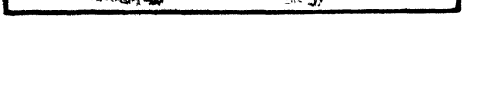
Oswego Serge is made of the finest wool and — quality considered — priced low.

Whether ordering a custom-made suit of your Tailor or a ready-to-wear suit of your Retail Clothier, insist on **Oswego Serge.**

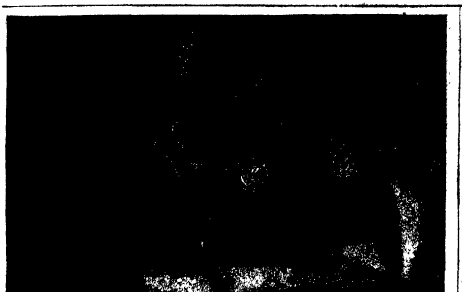
If unable to obtain **Oswego Serge,** send us the name of your Tailor or Retail Clothier, accompanied by money order or check for quantity desired, at $3.00 per yard, and we will see that you are supplied. Your Tailor will do the rest Samples furnished on request.

Special Fabrics For Out-of-door Clothing

TO MEET EVERY REQUIREMENT OF THE EXACTING SPORTSMAN, TOURIST OR MOTORIST



Forestry Cloth (Shade No. 65) as an out-door fabric is ideal, because dust and wind proof — sheds water — and being a beautiful shade of olive-green commends itself to the woodsmen, has been adopted by the U. S Government as standard for the Forestry Department Comes in several weights



Quivaute Cloth — a fabric similar to the above in weave made in an attractive shade of light brown and especially suited for riding and driving clothes, motorists' apparel, outing suits and raincoats.

These cloths are highest grade, pure all wool worsted, closely woven, very durable and uniform in color.

Samples of *Forestry Cloth* and Quivaute Cloth sent upon request If you are unable to procure these fabrics from your Tailor, we will see that you are supplied upon receipt of price. When ordering specify fabric and number of yards desired. *Forestry Cloth* $2.75; Quivaute Cloth, $3.50 per yard

The Haynes in the Royal Gorge

The Haynes Goes Everywhere

AND the best part of it is that ever since 1893 the Haynes has been going everywhere that any automobile could go Eighteen years of the history of automobiling are built into the 1912 Haynes. This means a whole lot to you who are considering the buying of your first automobile this year, or the buying of another to take the place of the old one that is worn out or isn't good enough.

This eighteenth year of the Haynes car is a year of triumph for the pioneer American builder of automobiles Last year automobile experts, and the public as a whole, declared the Haynes had reached the limit of quality production at a $2100 price It was hard to figure how any more automobile worth could be put into a car at the price of the splendid 1911 model, but there *is more* in the 1912 Haynes, and the price remains $2100.

The 1912 Haynes is not radically different from its recent predecessors. It is not radically better, but it does represent more all-round value than *anybody* has ever before been able to put into a car selling at the Haynes price.

The 1912 Haynes is a bigger car—120-inch wheel base: it's a roomier car—wider rear seat and more depth both in the tonneau and in front; it's a more powerful car—the 41x5½ motor gives forty to forty-five horse power: it's a safer car—larger brakes give one square inch of braking surface to every thirteen pounds of car and it is a snappier, more stylish car—the whole car is finished in black with seventeen hand-rubbed coats of paint, and the trimmings are of black enamel and nickel.

The 1912 Haynes is now ready for delivery. You can see them we models at our branches and agencies, or we will send you a catalogue and name of dealer nearest you. The line is complete, meeting every demand—5-passenger Touring, 40 h. p., $2100; 4-passenger, 40 h. p., Close-Couple, $2100; Colonial Coupe, 40 h. p., $2450; 7-passenger Touring, 50-60 h. p., $3000; 4-passenger Close-Couple, 50-60 h. p., $3000; Model 21 Limousine, 40 h. p., $2750; Model Y Limousine, 50-60 h. p., $3800. Complete regular equipment for all models is of the very highest class. Provision is made for the installation of electric lighting equipment at nominal cost. Address

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full lines to correspondents are printed from time to time and will be mailed on request.

(12533) Y. R. C. asks: In "Heavens in June" in your journal of June 3rd, it was stated that we could recognize Venus and Jupiter by the fact that planets do not twinkle. This I observed to be true. But according to your explanation given in query No. 12461, that distant lights twinkle because the strata of the intervening air change their refractive powers, it should not make any difference whether the light is from a planet or a star. Will you please explain it? A. The reason given by astronomers why planets do not twinkle is that they present apparent disks, and are not mere shining points as the stars are. Mercury, the smallest planet and the nearest to the sun, is always seen to be twinkling violently. This peculiarity of Mercury among the planets is due to its small size, so small that at its great distance from us it has no apparent disk, and its greater intrinsic brightness because of its nearness to the sun. See Todd's "New Astronomy," pages 92 and 313. We can furnish the book for $1.50.

(12534) F. A. C. says: Is it true, as I have often heard stated, that dry batteries will give better results (i. e., a better spark at same voltage) than will wet batteries; both batteries being in their best condition. Is this true and why? A. A dry cell is made to have a very low internal resistance and so to give a large number of amperes on short circuit It therefore is well adapted to give a very hot spark If a wet cell were made on the same lines it would give the same result. It is not the voltage of the cell which produces this result, but the amperes, and this is the quotient of the volts divided by the ohms in accordance with Ohm's well-known law.

(12535) W. L. S. asks: Has an article ever been published in the SCIENTIFIC AMERICAN describing a method of hypnotizing one's self and rendering one clairvoyant? Also do you know of any source of information that could furnish the desired data? A. We have had many valuable articles on hypnotism in our SUPPLEMENT. We name numbers 148, 299, 371, 587, 720, 756, 1047, 1056. We will send these papers for ten cents each We can also furnish you any book published upon the subject; we name Bramwell, "Hypnotism, Practice, and Theory," $4.50; "Hypnotism," by Moll, $1.50; "Hypnotism, How It is Done, Its Uses and Dangers," by Cocke, $1.50

(12536) C. R. asks: On the night of August 15th I observed a meteor in the southwestern sky which behaved different from any I ever before saw or heard of When first noticed it appeared a considerable distance to the left and above the apparent position of the planet Jupiter. At first it followed the usual wide course, moving toward the big planet across the sky. At the end of the long course the meteor turned sharply upward, its bright white light changing to a brilliant orange, quickly vanishing in a puff of black smoke Is it customary for meteors to behave in this way? What was the cause of such apparent erratic motions? Does the SCIENTIFIC AMERICAN sell any books on astronomy which would be worth while to own? If so, give prices, as I want to buy. A. While it may not be said to be customary for meteors to show the changes shown by the one you describe, still every sort of behavior is found in them Changing color and vanishing as if with a puff of smoke is not uncommon. We can supply you any book in print upon astronomy. You will find Prof. Todd's book very interesting and accurate. His "New Astronomy," price $1.50, is widely used as a text book, and his "Stars and Telescopes," price $3, is most interesting to anyone who looks at the heavens

(12537) H. R. G. asks: Will you please tell me what is the scientific explanation of the fact that a person can be lifted by the forefingers of two persons if they inhale at the same moment? A. It is safe to say that there is no scientific explanation needed for the fact that two persons can lift a person by their forefingers. The writer used to lift 150 pounds with one little finger, and feels no surprise that two persons should lift the same weight using four such straight fingers for the purpose. The inhaling of the breath diverts the attention of the persons from the act of lifting, and they usually say they do not lift at all. But to raise a person weighing 160 pounds, that weight must actually be lifted, and each finger must lift 40 pounds. This is a small weight for a forefinger to lift. We do not think there is any occult force in action here, but just a simple action of the muscular force. We have seen it done without any inhalation of breath at all, and just as easily as when inhaling the breath.

Science

Chinese and Japanese Bells.—Consul S. L. Gracey, stationed at Foochow, calls attention in the *Daily Consular Reports* to the soft and smooth tone of the bells in use at temples and monasteries in China and Japan. The quality of the tone is due not only to the use of excellent material, but also to the absence of iron clappers. The bells are never swung, but are always suspended in a fixed frame, and are sounded by striking them on the outer edge with a wooden mallet.

Masuchika Shimose.—Masuchika Shimose, who invented the high explosive to which the name Shimose powder was given by the Japanese navy, died on September 7th. He was professor of applied chemistry and was born in 1859. For several years he was superintendent of the ammunition department of the naval arsenal, during which time he made extensive researches in connection with explosives. His compound was adopted in 1893 by the Japanese navy, and for his services a decoration and a sum of money were granted to him.

Facts About Mastication.—The force required to crush an ordinary nut, such as one too often sees cracked between the back teeth, has been shown to be equal to a weight of more than 110 avoirdupois pounds, directly applied. The amount of saliva daily secreted by the average male adult is about 1¼ liters or 1.59 U. S. quarts. In thoroughly chewing 100 grammes of "Zwieback"—a kind of sweet toasted bread—there is needed half a liter (0.53 U. S. quart) of saliva; in masticating the same amount of apples, only 1.75 liter or 3.7 cubic inches; that is, only 8 per cent, or about one-twelfth as much.

A Shining Metal.—There is a legend among the peasants of Cornwall in England that at night there may be observed a faintly-shining mineral among the rocks brought from the mines. That this is not pure fancy has been proved by Prof. Strutt. A specimen of the mineral autunite, which is also found in Wales, was sent to him from Portugal because of its luminosity. He finds that it closely resembles artificially prepared salts of uranium, and that its luminosity is due to spontaneous radio-activity. The light it sheds is stronger than that of nitrate of uranium Upon parting with its water of crystallization the mineral loses its luminous property.

The Size of the Oceans.—The Pacific Ocean covers 68,000,000 square miles; the Atlantic 30,000,000; and the Indian Ocean, Arctic and Antarctic Oceans 42,000,000. To stow away the contents of the Pacific it would be necessary to fill a tank one mile long, one mile wide and one mile deep, every day for 440 years. Put in figures the Pacific holds in weight 948,000,000,000,000,000,000 tons. The Atlantic averages a depth of not quite three miles. Its waters weigh 325,000,000,000,000,000,000 tons, and a tank to contain them would have each of its sides 430 miles long. The figures of the other oceans are in the same startling proportions. It would take all the sea water in the world 2,000,000 years to flow over Niagara.

How We Ought To See.—Data have been gathered in Germany with reference to the distance at which persons may be recognized by their faces and figures. If one has good eyes, the Germans claim, one cannot recognize a person whom he has seen but once before at a greater distance than twenty-five meters (eighty-two feet). If the person is well-known to one, one may recognize him at from fifty to one hundred meters, and if it is a member of one's family, even at one hundred and fifty meters. The whites of the eyes may be seen at from twenty-seven to twenty-eight meters, and the eyes themselves at seventy-two to seventy-three meters. The different parts of the body and the slightest movements are distinguishable at ninety-one meters. The limbs show at one hundred and eighty-two meters. At five hundred and forty meters a moving man appears only as an indefinite form, and at seven hundred and twenty meters—2,361.6 feet—the movements of the body are no longer visible.

Let the Red Devil Water Motor Pump Your Water

Adapts Itself to Any Water Pressure

Delightfully Simple, Inexpensive, Absolutely Perfect, Pure Water Supplied Under Any Desired Pressure. Operates on Pressure as Low as 10 Pounds per Square Inch. Will Pump Water to Any Height, Through Any Length of Pipe, by Simply Increasing Pressure. Does Not Freeze, Rust, Clog or Get Out of Order.

Size, 5000 Gallons Capacity per Hour, $15.00 Each. Larger Sizes for Greater Capacities. Write Today.

Runs with Ordinary Water Pressure, Such as Is Found in Most Cities and Towns. Will Operate with Pressure as Low as 10 Pounds per Square Inch. Will Pump Water to Any Height, Through Any Length of Pipe, by Simply Increasing Pressure. Does Not Freeze, Rust, Clog or Get Out of Order.

Aeronautics

Fatal Aeroplane Accidents in America.—On September 2nd Captain John J. Frisbie, one of the most daring and best of our aviators, fell to his death in Kansas while making an exhibition flight. Frisbie did not wish to make the flight, but he did so to please the public. His machine, which was equipped with a Gnôme motor, is said to have turned completely over when flying in a gusty wind. On September 4th, Alexander McLeod of Winnipeg, Canada, fell from a Curtiss biplane while making a flight at Chicago. McLeod's neck was broken, and he was fatally injured.

The Transcontinental Flight.—The transcontinental flight for a prize of $50,000 offered by a New York newspaper, has drawn forth no less than eight entries to date. Besides Mr. Robert G. Fowler, the Wright pilot whom we mentioned in our last issue, the Wright aviators, Rodgers, Parmalee, and Atwood, and the Curtiss aviator, James J. Ward, are planning to compete in their biplanes, and Earl L. Ovington expects to attempt the flight in his Blériot monoplane. In addition to the above-mentioned aviators, Mr. James V. Martin expects to try for the prize in a new headless biplane of his own design, and Mr. A. V. Reyburn, Jr., of St. Louis, has also entered. Mr. Ward is making the chief effort to fly from New York and win the prize. He will be accompanied by a special train containing an extra machine and plenty of spare parts. The indications are that there will be a lively cross-country competition for this prize before the month is over.

Mr. Glenn Curtiss's Ideas on Aeroplane Development.—Glenn H. Curtiss has had more experience than any other man with regard to the naval aeroplane, and he has recently made a statement summarizing the points upon which the aeroplane needs improvement for military and naval use. He believes that the first requisite is the ability to fly under all sorts of weather conditions, especially in strong winds. His own machines have demonstrated their ability in this direction, as we have already noticed. The points of improvement given by Mr. Curtiss are the following: 1 Degree of safety when operated in rough weather. 2 Speed in altitude climbing. 3 Scope of vision of operator and passengers. 4 Facility for alighting on either land or water and rising from either at will. 5 Factors of safety in design and construction. 6 Weight carrying. In addition to these, further credits should be given for small extent of surface offered as a target, for ability of either occupant to operate the machine without inconvenience, for speed in packing and unpacking, and for facilities in launching the machine from a confined space.

Record Flights at the Boston Meet.—The Boston meet was brought to a close on September 6th after a number of record flights had been made. The chief of these was the 180 mile cross country race for monoplanes, with a $10,000 prize to the winner, which was flown on Labor Day. The course was from Boston to Nashua, N. H., to Worcester, Mass., Providence, R. I., and return to the aviation field at Squantum. Mr. Ovington, on his Blériot monoplane, and Arthur Stone on a Queen monoplane were the only competitors, while in a biplane race over the same course, Lieut. Milling, in a Curtiss, and Harry M. Atwood in a Wright, were the only competitors. Atwood carried his father as passenger, but only flew 12 miles before he was obliged to descend on account of motor trouble. The same was the case with Stone, who only covered about 10 miles before he was obliged to alight. Ovington completed the course in 3 hours and 4 minutes, alighting at each of the cities mentioned. Lieut. Milling lost his way before he reached Nashua and he was obliged to alight at Concord and inquire which way to go. Owing to this and other delays he did not finish the race until after dark. He was awarded the first prize of $7,500, his time for the flight being 5 hours and 23 minutes. Another feature of the meet was the winning of the 33-mile race to the Boston Light and back twice over, by Grahame-White in his Nieuport in 27-35 1/5. This is the fastest time ever made over this course.

"Fame Follows Where Everitt Goes"

The 1912 Self-Starting Everitt "Four-36" 106pc. Fully Equipped. $1500

The New Everitt Models—The "Six", The "Four" and the "Thirty" Are Ready For Your Inspection At A Nearby Dealer's—See Them

THE recent announcements of the 1912 Everitt have literally amazed the country. The values offered are so unusual and unexpected that it is little wonder their possibility has been freely doubted.

It has even been said, by some, that if such a car as the Everitt Chrome-Nickel Self-Starting Six could really be sold for $1850, no man in his right senses would think of buying any other if he could get an Everitt.

Other manufacturers have frankly admitted this. They did not see how we *could* do it; they did not believe we *would* do it.

But the proofs are open to anyone. The affidavits of famous steel-makers; an inspection of our factory; the record of the men behind the car—most of all, its own test, in your hands—show conclusively that these cars have really "bridged the gap between the $1500 price and the $4000 quality."

Chrome-Nickel Steel Construction

To those who know anything of fine steels, no argument is needed to show the superiority of Chrome-Nickel. A Chrome-Nickel Steel car—as any engineer can tell you—is about three times the usual strength.

The new Everitt Six and Four-cylinder cars are built throughout of this incomparable material, making them well-nigh unbreakable and unwearable in service. So far as known, these are *the only cars*, selling below $4000, in which this matchless steel is used to any extent.

This material comes from two of the best producers of fine steels in this country—the Billings and Spencer Company, and the Crucible Steel Company of America, at a cost of nearly three times what "good automobile steel" commands.

The affidavits of these two great concerns—showing beyond question that the Everitt is entirely constructed of Chrome-Nickel Steel—have recently been reproduced word for word in our public announcements.

Every Desirable and Modern Feature

In addition, these cars are provided with a Compressed Air Self-Starter which starts the motor and pumps the tires. The wheels are big and massive, and provided with Demountable Rims. The design is clean-cut and handsome, with all levers and door-handles inside. Full equipment, with everything of the best, is included.

Except for size and number of cylinders, the new "Four" shown above, is practically a duplicate of the "Six". Both these cars, with the famous "Everitt Thirty," are beyond comparison from the standpoints of reliability and service.

We invite you to see these new models at your earliest opportunity. The brief specifications of the Everitt "Four-36" are as follows:

Wheelbase, 115 in.; Wheels and Tires, 34 x 4 in.; Horsepower 36; Demountable Rims; Honey Comb Radiator; Long Stroke Motor; Compressed Air Self-Starter and Tire Pump; Chrome-Nickel Steel Construction Throughout; Top; Windshield; Speedometer and Prestolite included. Price, $1500

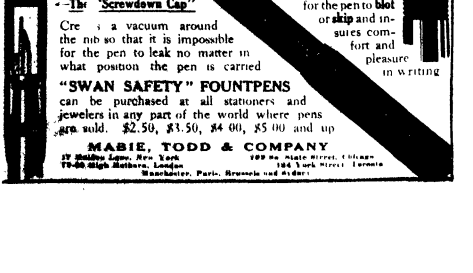
THE SWAN SAFETY FOUNTAIN PEN

BUILT ON SCIENTIFIC LINES

The "Gold Top Feed"



Keeps the pen point or nib wet with ink so that the pen writes the minute it touches the paper.

The "Ladder Feed"

Controls the flow of ink, supplying the exact amount necessary—no more—no less. This special feature makes it impossible for the pen to blot or skip and insures comfort and pleasure in writing.

The "Screwdown Cap"

Creates a vacuum around the nib so that it is impossible for the pen to leak no matter in what position the pen is carried.

"SWAN SAFETY" FOUNTPENS

can be purchased at all stationers and jewelers in any part of the world where pens are sold. $2.50, $3.50, $4.00, $5.00 and up

AVIATION

The OCTOBER MAGAZINE NUMBER of the SCIENTIFIC AMERICAN ISSUE OF OCTOBER 14th, 1911

The next mid-month number of the Scientific American will bear the date, October 14th, 1911.

A large part of the number will be devoted to the more practical aspects of flying.

Of these aspects, perhaps the most dramatic, the one which interests the casual reader most, is the use of the flying machine in war. In an article entitled "Dropping Bombs from Aeroplanes", Lieut. Scott draws a vivid picture of the conflict of the future, and tells in what manner the soldier of the air will direct his course over an enemy's camp, and drop shrapnel upon the helpless troops beneath. The chief problem to be solved is that of directing the projectile accurately, which phase of the subject Lieut. Scott discusses with the fullness and directness that may be expected of a West Point man.

In three recent European races, Lieut. Conneau won $100,000. The sum is huge, but not nearly so huge as other figures in this newest of industries. In an article entitled "The Business Side of Aviation", Mr. Grover Cleveland Loening will tell what it costs to race, what a flight like that of Atwood's from St. Louis to New York means in dollars and cents, what enormous profits are made by the manufacturers of aviation motors and aeroplanes themselves.

Not until the engineer steps in and designs a machine which will fly fast with the least possible engine power will the aeroplane take its place as a pleasure vehicle which any one may use. Much scientific research is necessary before that time will come, to determine the best form of plane. What physicists are doing in the laboratories of great universities to solve that problem is revealed in an article which bears the title "Progress in Aerodynamics".

Every amateur who takes the most superficial interest in aviation considers himself competent to design an aeroplane. He knows nothing of the basic principles laid down by Langley, Chanute, Maxim and the Wright brothers. The result is machines that are aviation absurdities. In a merrily written and biting article, which is fittingly entitled "The Chamber of Horrors", these freaks are riddled.

Besides these articles on aviation, the mid-month number for October will contain the usual Scientific American material, abstracts from current periodicals, the inventor's department, and articles on recent achievements in science and industry.

The whole number will be incased in a colored cover by Mr. William Hamden Foster.

Price ten cents on all news stands.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are strong, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Newspaper Heroism

THE true professional spirit is essentially modest, and among the highest type of professional men the good of the cause ranks higher than the gain of the individual. Pride of place and a laudable ambition to excel go side by side with a settled dislike of limelight exploitation and any form of newspaper notoriety. The ethical distinction between the trades and professions, which was so strongly accentuated in earlier days, and survives in certain parts of the world even to-day, was based originally upon the fact that the professional man was supposed to take up his life's work primarily because he loved both the profession and the people whom it might benefit. The personal gain which it brought was a secondary consideration. In this respect he was distinguished from the man of commerce, who bought and sold first and last for pecuniary gain. This ethical distinction or dividing line between the trades and professions has largely disappeared, and we are sufficiently optimistic to believe that it has been due to a filtration of the professional spirit into the commercial world.

A case in point occurred on the steamship "Carmania" when she recently put into Halifax for coal, and took advantage of the opportunity to make some minor repairs to her low-pressure turbine. A small leakage pipe, leading from the turbine to the condenser, had developed signs of weakness, and it became necessary to close certain gates which were inaccessible from the exterior of the engine. Ordinarily the turbines would have been allowed to cool down for repairs of this character, but in order to save from six to eight hours' time, which would be necessary for cooling off, the engineers decided to take off the manholes and send one of their number in to close the gates. This was done, and although the internal temperature was about 175 degrees, the task was successfully accomplished.

Upon the arrival of the ship in New York the event was seized upon by the daily press reporter, and a repair job which was designated by the engineers themselves as a mere matter of routine duty, was magnified into a story of stupendous heroism and magnificent devotion to duty which, although it may have provided an interesting quarter of an hour for the average citizen over his morning cup of coffee served with just provoke mingled consternation and ridicule among the engine room staff of the ship itself. Although a temperature of 175 degrees is scarcely that in which the average individual would choose to take even moderate exercise, it is a fact that in some engine rooms, especially in the tropics, temperatures have been known to run up not so very far from that given. On certain warships, when the hatches are battened down for battle practice, engine-room temperatures have been known to run up as high as 165 degrees.

A Safety Throttle for Locomotives.

PROMPTED by the too frequent instances of the disablement of locomotive engineers, either by accident, sickness or sudden death, a correspondent suggests that all locomotives should be equipped with some form of automatic "safety throttle," similar in its action to the control levers on the motors of the New York and Boston subways which automatically cut off the power the instant that the pressure of the driver's hand is removed.

Some years ago the editor rode in the cab of one of the then newly-instituted 18-hour trains to Chicago, when he covered some 1,500 miles of the round trip in the locomotive cab. He noticed that generally, and particularly at night, the engineer would keep one hand upon the throttle, the other upon the air brake lever. An emergency stop was made by the instant operation of these two levers. It would, of course, be possible by means of some source of power, *such as a pneumatically-controlled* piston, to shut off the steam and apply the brakes at the instant that the engineer's hand dropped from the throttle, either through accident or death. The objection to such an arrangement would be that there are times when he must remove his hand from the throttle, as for instance when it is necessary to sand the rails or open the cylinder drain cocks. On the other hand, the safety stop might be so arranged that it could be temporarily locked in position at the will of the engineer. In these days of huge boilers and large fire boxes, it becomes increasingly difficult for the fireman to supplement the watchfulness of the engineer. Locomotive engineers as a body would welcome, we believe, any practicable safeguard of this character, and it would materially add to the safety of railroad travel.

A German Criticism of the Panama Canal

THERE recently appeared in *Prometheus* a review of conditions and prospects at the Isthmus of Panama, which may probably be taken as representing the average German view of our stupendous task of cutting a waterway from the Atlantic to the Pacific at that point.

It takes but a cursory reading of the article, which will be found in full in the current issue of the SUPPLEMENT, to convey the impression that the writer is strongly pessimistic, both as to the completion of the canal in 1915, and as to its commercial utility after it has been thrown open for traffic. American reports of rapid progress are considered to be "very optimistic"; "extraordinary obstacles have yet to be overcome"; and "the officials responsible for the canal are beset by worries and fears."

Of the five kinds of difficulties—sanitary, financial, technical, geological, and commercial, enumerated by *Prometheus*, it is admitted that the Americans, who have proved themselves masters of the art of sanitation, have surmounted the hygienic and climatic obstacles which all but prevented the construction of the Panama Railway half a century ago. Seeing that the United States regards it as a matter of national honor to carry the work through, the financial basis of the enterprise is considered to be secure.

It is easy for any one who is familiar with the canal problem to predict the line of criticism which will be followed by any one who approaches the unusual geological and technical difficulties which the construction of the canal has opened up. In the present case, the security of the Gatun Dam and the permanence of the slopes of the Culebra Cut are called in question, but in neither case is any new light shed upon the subject, nor are any possibilities of failure suggested which have not been made the subject of careful study and practical experiment by the engineers in charge of the work. An experimental dam has demonstrated that the materials used in the hydraulically built-up Gatun Dam will be proof against seepage; and there is no evidence that any continuous and out-cropping strata of pervious material is to be found in either of the two underlying geological gorges, which will form part of the foundation upon which the dam will rest. Compacted by the great weight of the overlying dam, 120 feet in height, the underlying material, as revealed by hundreds of borings, is such that there is every reason to believe that the sub-surface, thoroughly compacted by the enormous weight of the overlying dam, will prove to be as water-tight as the dam itself. It is true, as *Prometheus* states, that "this construction has been much discussed and severely criticised in America"; but it should be noted that this criticism was made before the extensive borings and the carefully carried out tests had demonstrated to the satisfaction of our engineers that the structure will be stable and secure against seepage.

Regarding the unquestionably serious slides in the Culebra Cut, to which much attention is given, it is sufficient to say that these slides were expected and provided for in the estimate of final cost. The unstable character of the Culebra Mountain had been suggested by the experience of the French when they commenced the cutting, and further established by the borings made by the American engineers. An estimate of six million dollars was made by Col. Goethals to cover the probable extra cost of removing the slides. The latest advices from the Isthmus are to the effect that on the more important of the slides, the movement appears to have ceased, and that present indications show that the appropriation will be sufficient to cover any further movements of this character. Certainly it is not true that the "heavy rains and floods sometimes make the most careful and elaborate calculations utterly useless." Careful records of climatic conditions for many years past have made it possible for the engineers, by basing their calculations upon the maximum rainfall and maximum flood discharge, to make ample provision for every possible contingency.

Finally and inevitably, the writer in *Prometheus* brings to the front the old bugaboo of damage by possible earthquakes, although it is distinctly to his credit that, unlike some American critics, he impartially points to the fact that the Panama region is comparatively free from such violent earthquakes as frequently occur in Central America. The last earthquake of a violent character took place in 1621, nearly three hundred years ago, and since then the Isthmus of Panama has experienced only very slight shocks, the most notable of which occurred in 1882. It is our own belief that slight disturbances of this character would have no material effect either upon the earthen dams or the concrete locks. Furthermore, we believe that because of their great mass, not merely the dams, but the locks themselves, would pass through an earthquake of some severity without either fracture or displacement.

We are free to admit, however, that, when our critic comes to the question of the commercial future of the canal, he is much more to the point. He considers it doubtful if the Panama Canal is destined to become the "important artery of commerce and the worthy rival of the Suez Canal that it is designed to be," believing that it makes its appearance too late to render to civilization the service that it might have rendered at an earlier date in the history of the commercial world. Had the canal always existed, the history of development might have been very different, the northeastern part of the Pacific Ocean would not have remained almost unknown until the middle of the nineteenth century, and the route of traffic between Europe and Australia and eastern Asia would have been via Panama, and would have become so established that it could scarcely have been diverted by the construction of the Suez Canal. But the development of the present trade routes has been based on the absence of a Panama Canal, and the great question is, how far can the opening of this waterway serve as a diversion?

The writer believes that the existence of the eleven trans-continental roads in Canada and the United States, and the recent opening of similar routes across South America, to say nothing of the excellent Tehuantepec Railway, have largely removed the trade necessities which, in former years, called so loudly for the construction of the Panama waterway. Very significant is his comparison of the values in millions of dollars of merchandise which was shipped from American ports to both American and foreign ports, via Panama and Tehuantepec, in successive years from 1907 to 1910. In 1906-7 the value for Panama was $9,600,000, in 1909-10 this had risen to $12,800,000. The value for the Tehuantepec Railway for five and one-third months in 1906-7 (the year of opening), was $11,450,000, and in 1909 to 1910 this had risen for the twelve months to the astonishing total of $69,600,000.

How far the forecast of this German review will prove to be correct, time alone can tell. It is our opinion that the advantages of shipment from port to port, without breaking bulk, will prove to be too great for successful competition either by our own trans-continental railroads, or those of Mexico and Central and South America. The appearance of this ably-written article, however, is another proof of the careful study which foreign nations are making of the commercial aspects of the canal. It is quite a question whether our own commercial bodies and the federal government are giving this subject the early attention which it requires. If the general commerce of the United States and the interests of its merchant marine are to reap the legitimate fruits of this great national undertaking, we should take early steps to safeguard our interests by suitable legislation. It would be perfectly proper to pass a law extending to all commerce between United States ports on the Atlantic and Pacific by way of the canal, those benefits which are secured by our present coast-wise traffic—in other words, Congress should recognize such traffic between American ports via the Canal as forming part of our coast-wise traffic by excluding all foreign ships from participation therein. The passage of a law to this effect would unquestionably prove to be a most effective means for promoting the upbuilding of the American merchant marine.

Henry Walter Nernst

A Great Physical Chemist

By Prof. William J. Humphreys, United States Weather Bureau

THE present director of the Physico-Chemical Institute of the University of Berlin, Prof Henry Walter Nernst, was born at Briesen, West Prussia, June 25th, 1864. He is, therefore, a much younger man than the volume and importance of his work would lead one to suspect.

Intimate glimpses of a scientific man's daily life are often full of interest, especially when they reveal peculiarities or seeming eccentricities due to the nature and intensity of his work. In the present instance, however, these peculiarities will be left to the discussion of his intimate friends, whom, doubtless, they sometimes amuse but never offend For the rest of us the name Nernst calls to mind chiefly a number of important contributions to the science of physical chemistry, and hence it is with these alone that the following is concerned.

In order to get a proper appreciation of Nernst's contributions to human knowledge, it is necessary briefly to review the cultivation of that fertile field of science that lies midway between the chemistry of Lavoisier and the physics of Newton

As a matter of fact there is not now, and never has been, a sharp boundary between physics and chemistry. Hence a great mass of information that to-day would be grouped under the general heading, "Physical Chemistry," was accumulated long before any one ever thought of the above compromise title for it. Physical chemistry, then, in the sense of a knowledge of the physical properties of compounds, is not a new science The melting and boiling points of many substances, their specific heats, atomic and molecular volumes, viscosities, spectra, powers to refract light, to rotate the plane of polarization, and the like, were long ago studied, as were also the changes in these properties owing to the addition or substitution of one or more elements

The object of the earlier experimenters was exactly the same as that of the ablest of the later investigators All sought, as every student of nature must, to *co-ordinate* apparently isolated facts through broad generalizations, or the assignment of them to a common cause But while the experimental facts discovered by the earlier workers are of the greatest importance, only empirical and hence merely approximate relations were found.

The glory of the newer physical chemistry, that which justifies its claim to a position among the sciences, is the freedom of its laws from mere empiricism, and the exactness with which it enables one to calculate results by rigid mathematical processes It is to this branch of chemistry, the branch that might even be termed mathematical chemistry, that Nernst has chiefly contributed It must not be supposed, however, that he was the founder of this our newest science, for there are others, especially Ostwald, van't Hoff, and Arrhenius, with prior claims to that honor; but he has been and still is one of its chief builders.

One of Nernst's earliest contributions to physical chemistry was a rational explanation of the mutual effect of salts upon each other's solubility It had long been known that in many cases two salts markedly interfere with each other's solubility in water, while others do not so interfere; but no satisfactory explanation had been offered for this phenomenon, nor was it possible, with a knowledge of the substances themselves, to predict what effect either would have upon the solution of the other. In this case, however, as often happens, the data necessary and sufficient to a complete solution of the problem were at hand, but it was Nernst who had the inspiration and the ability to use as premises the law of mass action, as developed by Guldberg and Waage, and Arrhenius's theory of electrolytic dissociation, and from them logically to deduce the exact cause and numerical extent of the effect of one salt on the solution of another

Another of Nernst's many contributions to our knowledge is an explanation of why any dissolved substance, as cane sugar, for instance, gradually spreads or diffuses throughout the medium in which it is dissolved Here use was made of the laws of osmotic pressure as formulated by van't Hoff—laws that in every particular are analogous to the laws of gas pressure.

Just as difference in gas density leads to gas diffusion, so does difference in concentration of a dissolved substance lead to its diffusion through the medium in which it is dissolved Hence the distribution of osmotic pressure throughout a given solution determines both the direction and velocity of diffusion

During recent years the investigation of chemical equalibra at high temperatures has occupied most of Nernst's attention As every one knows, the properties of substances depend upon temperature. Up to a certain temperature iron, for instance, is easily magnetised, while at higher temperatures it is but slightly magnetic At ordinary temperatures rubber is exceedingly flexible and elastic, but at the temperatures of liquid air it is as brittle as glass And so it is with other substances, their properties are profoundly modified when the temperature is greatly changed, so that to know a substance thoroughly is to know its properties at all temperatures Nor are the physical changes with temperature more pronounced than are the chemical. Substances that combine at one temperature decompose at another, and qualities that are in a state of chemical equilibrium at one temperature are thrown out of balance by heating or cooling Hence change in temperature furnishes unlimited studies for the physical chemist—studies to which Nernst and his students have given the most attention, but with results which, while valuable, necessarily are still incomplete The subject is so vast and so difficult that it will require years of work approximately to complete it

Probably the general public, since it cares more for an art that serves its needs than it does for the science that rendered the art possible, knows of Nernst chiefly, if not solely, as the inventor of the electric glower that bears his name This, however, like practically all other discoveries worth while, was the outcome, or, more exactly, a by-product of a purely scientific investigation, a careful study of the electrical conductivity of solid electrolytes In the course of this work it was found that the oxides of certain rare elements possess properties that adapt them to economical use in electrical illumination This was the always necessary discovery, the rest, in rendering the glower practicable, was but the ingenious combination of things already known.

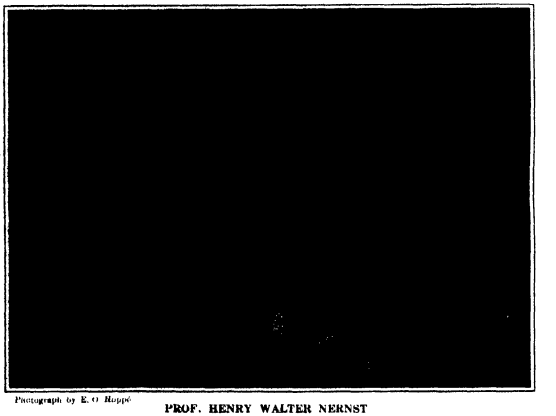
To the scientific world, however, Nernst is best known as the man who first developed a satisfactory theory of the action of the primary electric cell, a theory that enables one to calculate beforehand just what electro motive force will be generated by a given combination of elements and solutions

The theory in question is based on three things, namely

(a) van't Hoff's laws of osmotic pressure or tendency of a dissolved substance to move from places of greater to places of less concentration

(b) The electrolytic dissociation theory of Arrhenius, which accounts for certain properties of dissolved salts on the assumption that they are more or less broken down into their constituent parts and that these individual parts are electrified

(c) Nernst's theory of solution tension or the assumption that any metal, when placed in a liquid, even a solution of one of its own salts dissolves to a certain extent, just as a liquid evaporates



The theory of the action of primary cells not only accounted for the actions of all known cells of this nature, but even suggested previously untried combinations and foretold their action

An exceedingly simple cell but one that illustrates the theory, consists of two zinc rods dipping, the one into a concentrated, the other into a dilute water solution of zinc chloride The tendency of the zinc to dissolve into the water—its solution tension

Is the same in the two cases, but the osmotic pressure of the zinc ions furnished by the zinc chloride is greater in the concentrated than in the dilute solution Hence since the osmotic pressure and the solution tension are in opposite directions, a *state of equilibrium* requires a larger number of zinc particles to be dissolved from the zinc bar in the weak solution than from the one in the strong solution But each zinc particle carries with it a definite charge of positive electricity, and consequently both zinc rods are left negatively charged though the one in the dilute solution is more strongly charged than is the one in the concentrated solution Therefore when the two zinc rods are connected by means of an electrical conductor and the circuit is otherwise properly completed, a current flows from the less negatively to the more negatively charged rod outside the solutions, and in the reverse direction within the solutions This of course destroys the balance, in both solutions, between the solution tension and osmotic pressure In the diluted solution the advantage, after the balance is destroyed, is on the side of the solution tension, while in the more concentrated solution it is with the osmotic pressure Hence zinc is dissolved and added to the dilute solution from the rod that is in it and at the same time an equal amount removed from the other solution and deposited on the rod it contains, till, in the end the two solutions are of equal strength

At all times, and in all similar cells, the electro motive force is directly proportional to the logarithm of the difference between the two osmotic pressures and is numerically calculable

Such, then, are some of Nernst's important contributions to science, and there is every reason, judging from his industry, ability and position to expect still others of great value

Photograph by E. O. Hoppé

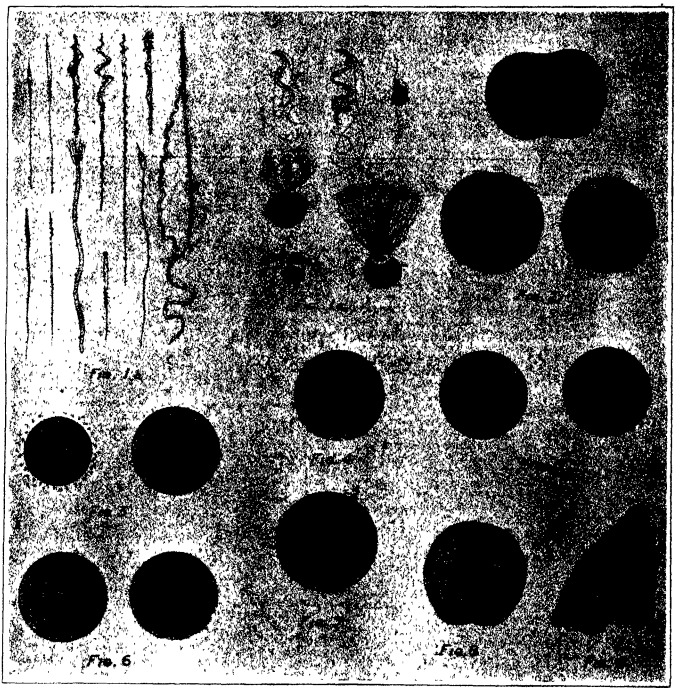
PROF. HENRY WALTER NERNST

New Life Preserver

RECENT consular reports describe a new form of life preserver, which it is proposed to introduce into the German Navy It consists of two swimming cushions bound together by straps and arranged to lie upon the breast and back The novel feature of the apparatus is an electric lamp, which is worn on the forehead The lamp burns 3 or 4 hours and is provided with a reflector which throws its light for a distance of several hundred yards at night The life preserver can be buckled on in 5 seconds

Artificial Life

II. Making the Non-Living Do the Work of the Living



By Benjamin C. Gruenberg

We have seen that the body of scientific research which has to do with what is popularly termed "artificial life" takes on two distinct phases.* The first has to do with the creation of an artificial system or "machine" which behaves more or less like a living body, or like the living substance called "protoplasm." The second has to do with causing eggs to develop without being fertilized—"artificial parthenogenesis."

Before the discovery of the sperm in the seventeenth century, the nature of fertilization was absolutely unknown. It was in 1677 that the Dutch scientist Lieuwenhoek first saw the sperms of certain animals, but these swimming cells were at first regarded as parasites. The assumption among men of science was that the essential thing in fertilization was the fluid in which the sperms float. But the Italian monk Spallanzani, who was in some ways ahead of his time in his methods, filtered some spermatic fluid and showed that the sperms were the essential factors. This was more than a hundred years after the little "animalcules" had been discovered and still nothing could be known of the nature of fertilization, because nothing was known of the nature of the egg. After the establishment of the "cell theory" of the structure of living things in 1838-39 it was possible to get the notion that the egg is a *cell*; and a few years later (1845) the actual union of sperm and egg cells was directly observed, although the sperm was not yet recognized as being also a cell until twenty years later. During all these years, however, there was an abundance of speculation. This concerned itself with two major problems which overlap in parts. The first is: how does a hen's egg, for example, become metamorphosed into a chick? The second is: what is the share of each parent in the developing egg?

The first of these questions *could* not be answered in the latter part of the eighteenth century when speculation probably reached the high-water mark. There were two leading theories, with endless argument and debate. According to one theory the egg contained within itself a minute duplicate of the parent, and that this simply grew and developed. The extreme exponent of this "preformation theory" was the French naturalist, Charles Bonnet, at whose hands it developed into the absurdity that the parent bore these eggs with their preformed minute embryos while she was still herself in the egg, and so on indefinitely to the beginning of life. This doctrine was later abandoned by Bonnet, and had very few adherents. But, as we shall see, there was more in it than its strongest advocates ever suspected. The alternative view was that the egg started as a body without any definite structure, and developed the complex structure gradually. This idea of "epigenesis" was forwarded by Caspar Friedrich Wolff, who had the sense to abandon speculation and resorted to observing what could actually be seen in the developing hen's egg. But this doctrine did not carry satisfactory conviction.

The second question above referred to, that of the share of each parent in the developing egg, was also chiefly the subject for speculation and dispute. According to one school, the essential thing is the egg; the sperm serves merely as a stimulus for development. According to the other, the sperm is the essential thing, the egg merely supplies the nutriment for its development. Since 1875, however, we know that both elements enter into the make-up of the developing cells. In this year Oscar Hertwig and other biologists were able to observe directly the union of elements from the egg nucleus with elements from the sperm nucleus (Fig 2).

1a, Sperms of various plants. 1b, Sperms and eggs of various animals. 2. Fusion of nuclear elements from sperm and egg in fertilization. 3a, Unfertilized sea-urchin egg surrounded by sperms. 3b, The same after the entrance of a sperm and the formation of a "fertilization membrane."—After Loeb. 4. Beginning of the first nuclear division in fertilized egg.—After Loeb. 5. Completion of the first cell division in the segmentation of the fertilized egg.—After Loeb. 6. Four-cell and eight-cell stages in segmentation of the egg.—After Loeb. 7. Hollow ball of cells; the "blastula" stage in the development of the sea urchin and other animals.—After Loeb. 8. Two-layered cup of cells, the "gastrula" stage in the development of the sea-urchin and of other animals.—After Loeb. 9. The "pluteus" stage in the development of the sea-urchin larva.—After Loeb.

EGGS AND THEIR DEVELOPMENT

The debate between preformation and epigenesis has now no real meaning. Epigenesis is true in the sense that the fertilized egg from which the organism develops does not contain any preformed structure corresponding to the anatomy of the plant or animal into which it is to develop. On the other hand, the preformation theory was true in this sense: the fertilized egg cell contains elements that were present in the parents, which in turn derived them from their parents and so on indefinitely. In other words, the question that these speculations attempted to answer is in reality two questions: one has to do with the mechanics of development, the other has to do with heredity. The fact of fertilization has also this double aspect: it introduces into the egg the elements that make up the heredity from the male parent; and it starts the activity of the egg that leads to development.

These two aspects of fertilization have been experimentally demonstrated in a number of ways. The relation to heredity is shown by the fact of hybridization; indeed, it is through the study of hybrids that we have in recent years gathered the bulk of what we know about heredity. That the elements which "bear the heredity," or determine in some way the character of the organism, are carried by the nucleus was shown in an experiment by Boveri.

He cut the eggs (unfertilized) of sea-urchins, so that some pieces were without nuclear matter. These pieces he placed in sea water containing the sperms of another species of sea-urchin; the sperms fused with pieces of egg protoplasm. The egg began to develop, and when it got far enough along to be identified, it turned out to have the characters of only its male parent. As the nucleus cannot be removed from a sperm-cell without killing it (since the sperm is practically all nucleus) the reciprocal experiment cannot be performed. But the same results are obtained if an egg is made to develop without fertilization.

There are many animals and plants whose eggs normally develop without fertilization—either regularly, or under special conditions. For example, plant lice produce during the warm weather large numbers of eggs which develop into organisms like the mother without being fertilized, although another series of eggs, produced in the fall, cannot develop without fertilization. The same is true of certain species of "water fleas." The queen bee sometimes lays eggs that develop without being fertilized; these always develop into drones, and occasionally a worker-bee lays eggs which also develop without fertilization. This phenomenon is called *parthenogenesis*, and attempts to produce parthenogenetic development artificially have been made for a long time as it was expected that by this means we could get a clue to the physico-chemical

Central Station Current for Farms

Advantages of Introducing Electricity into Rural Districts

By T. Commerford Martin and Putnam A Bates

UP to the present time, with 6,000 central station companies in the United States, there has never been a company or plant established to supply electricity to a farming region Perhaps there never will be Conditions in the central station industry have changed so rapidly in thirty years that electrical supply, once the peculiar enjoyment of residents in a limited city area is now available, from the one source, over hundreds of square miles The Boston Edison company, which began twenty-five years ago with a little area of perhaps half a mile around Faneuil Hall, now covers a large part of Massachusetts with its circuits, and has many farm supply problems on its hands. Around Chicago, the North Shore Electric Company furnishes 24-hour current to a population of 250,000, in an area of 1,200 square miles, reaching 71 cities and towns, and some hamlets with barely 100 people. It has already many farmers on its books, and will soon have many more on its lines. The Public Service Company of New Jersey covers with its circuits the whole of the northern part of the State. Out in California, from the Sierras, electrical energy is fed to San Francisco over 200 miles away, and the circuits of the one system embracing more than half the counties in the State, are availed of already by many a farmer who never expects to have a railway track laid in front of his barn yard It has been proposed to throw into 25 or 30 plants, the generating capacity of all the 400 existing central stations of New York State, because it is so easy now to distribute electricity that is made economically in great quantity. In England, the idea has boldly been put forward by Ferranti of using in about 100 central stations 60 million tons of coal, to supply the whole country, farmers included, with electricity at as low a price as ¼ cent per kilowatt hour—1 1/3 horsepower for an hour for half a farthing. Here in varying instances we have reality and dream, but all emphasizing the immense fact that electricity has ceased to be the servant merely of the city population, and now regards as within its reach any populated district where poles can be set and wires strung.

It is needless to go into the technical details of the process of engineering and invention to which this expansion must be attributed. Three main factors are involved, namely, the adoption of the alternating current, the utilization of water powers, and the resort to higher pressures of current. Of all these changes the farmer is especially the beneficiary at present, and destined to be even more so in the near future. The methods of supply have been tried out and firmly established The questions now confronting the central station manager, and already being dealt with by him in a great many instances are those of specific local distribution and service Sometimes the farmer has still to consider the problem merely for himself The farmer may install his own private electric generating plant, or several neighbors might band together and construct a power station of their own, each being served on the co-operative plan The most extensive use of electricity, however, in the rural or farming districts will, unquestionably, come as a development of present central station systems or the organization of companies having as their prime object, the serving of farmers' needs, through well planned electric plants located in the heart of the agricultural sections

During 1910-11 a canvass was made by a committee, specially appointed by the National Electric Light Association, to investigate the work of the various central stations in its membership in developing and caring for the electric power and lighting service to farms and in rural districts The result of this canvass was embodied in a report prepared by this rural electric service committee, of which Mr J G Learned was chairman, and presented before the National Electric Light Association's annual convention, May 29th, 1911. The evidence brought out in the report is most interesting and encouraging

Interesting data and valuable suggestions are, therefore, now before us on this new problem of extending central station electric service to the farmer In mapping out territory, the central station can no longer regard the outlying sections as of no immediate concern. They are to be reckoned with, and preparations should be under way to develop this business along lines that would insure handling it on such a basis as will give satisfaction to the farmer, and be profitable to the service company

It is clear, from the reports of several electric plants, where the rural business has been developed along good engineering lines and the farmer assisted in the solution of his somewhat complex mechanical farm problems, that this service is profitable Other central station companies are now making elaborate plans for carrying out methods of farm supply

The uses to which electricity can be advantageously applied in rural districts are many, and far more in fact than one would at first suppose. For reasons of safety and labor saving, the need for electricity is really greater in farming districts than in the more densely populated sections owing to the comparative isolation and consequent difficulty in obtaining labor. In the agricultural sections where stock farming is carried on or where there is considerable water to be pumped for irrigation purposes the use of electric power is well recognized as a decided betterment and it is in such districts, largely, that one will find the greatest opportunity for immediate progress

Broadly stated, the stock breeding and stock feeding districts require more power than truck gardening districts A stock farm requires to have conveniently within its reach at least 25 horsepower for feed grinding ensilage cutting, threshing pumping and a variety of similar uses The operation of dairies and creameries also requires considerable power and is an inviting field for the use of electricity

Naturally, the farmer is not compelled to use electricity, for there are several types of agricultural power apparatus utilizing steam oil heated air or other source of energy, which may usually be employed at a somewhat less first cost but the convenience, absence of risk and cleanliness of electric service are features which he values It is not necessary therefore to exert much effort in explaining the advantage of electricity, but the question is on what basis shall the service be supplied?

The conditions incident to the supply of electricity in the rural or farming districts differ so materially from those in the towns and cities that when the "farm" is considered, one is in the habit of regarding the proposition as undesirable, because one does not clearly see the manner in which such service may be economically rendered nor the extensive uses to which electricity may be applied in agriculture This ignorance is not a universal condition by any means but it is illustrative of the atmosphere surrounding many central-stations, located adjacent to good farming sections

In northern Colorado, we find a progressive company that apparently has attacked the problem in the right manner, and some of the characteristic features of the service supplied are illustrated in the accompanying photographs In the center of the more thickly settled sections, sub or distributing stations of the type shown in Fig 1 are erected the object being to locate points to which to build heavy distribution feeder lines and from these substations as centers to feed out lateral branches

This system embodies good engineering methods

and makes the current transmission costs such that for farmer business the same rates are charged as those asked within the towns, the only difference being that a minimum charge is made to insure a reasonable return for the extra investment in the pole lines, the first cost of which this central station company finds it agreeable to bear

The planning of this system has been carefully done and the company's policy is to encourage the utilization of its current The soliciting agents are trained in the uses to which electricity may be efficiently applied in farming and their success in securing results and business rests solely on their power to convince the farmers of the merit of each idea suggested.

It is quite natural that the rural consumers will require more individual attention from electrical solicitors, owing to the entire reliance of the farmer on this source for information This makes farmers somewhat more expensive to care for as customers, but in the period of development it is money well spent as friendship is created or cemented and new uses are found for current

An especially desirable feature of the farmers' service is the fact that the power or principal portion of their current requirement is entirely during the day time, which makes a tendency to balance up the load on the power station without adding to the "peak" load conditions It is therefore, obvious that many plants in smaller cities can supply farms during the day and their urban customers at night, from the same generators

Figs 2, 3 and 4 illustrate water electrically pumped, for irrigation purposes, which is an important field for the use of power in any agricultural section

Fig 2 shows a small inexpensive housing for the electric pumping plant, which elevates the water from a reservoir, a corner of which is shown in the background The water is delivered from the pump through a system of trenches upon an acreage of sugar beets In nearly all western States it is impossible to raise fruit, grain or garden crops without the aid of irrigation Everywhere crops would gain if irrigation were more general

Gravity irrigation is not always possible, due to the level of the land with respect to the water source To irrigate these high lands, which are often more valuable than the lower lands, it is necessary to raise the water by pumping.

A general view of one of these electric pumping equipments is illustrated in Fig. 3, while Fig. 4 shows quite another condition, in that the land of this particular field is so low that water would naturally collect in places, forming marshes The pumping equipment seen in Fig. 3 is utilized to keep this field drained during the season of irrigation; and the large field of potatoes—the foreground of the illustration—receives the benefit of this water

The central station system above referred to, and of which these illustrations are photographs, would be entirely appropriate as a means for mastering the farmers' electric service problem in any locality, and while the uses to which electricity may be applied differ in the various localities, these illustrations are especially significant The more extensive use of irrigating methods and power applications for general purposes must be adopted in successful farming systems of the future This fact at once suggests a new field for the central station service that will no longer be neglected.

It was the introduction of electric motors that enabled manufacturers of all classes to determine definitely their power costs The results thus obtained, through the elimination of belting and shafting losses and by measuring directly effective power used, were surprising.

On the farm, the advantages of such a change lie in another direction The saving in power is not so important, for the amount of energy needed for this purpose is never so great as in the manufacturing establishment The "ever ready" feature of the electric motor is here its chief advantage. Moreover oils and other combustible fuels, useful as they are, always introduce a decided additional fire risk wherever used, and of necessity farms are isolated in outlying districts away from organized fire protection Small power engines, using gas or oil fuel, may be placed at a distance from buildings when in operation, which of course is safer, but not so convenient The danger, however, cannot be so readily lessened in the use of oil lamps, matches and lanterns, nor is it very convenient to have to go outside to a point distant from the central buildings whenever power work is done.

It is the inconvenience of things that often spells failure for farmers. With a minimum of labor at command and a maximum of work to do throughout most seasons of the year, a direct saving in time of getting ready on each operation is all important.

From this point of view, therefore, the utilization of central station electricity for farming sections within striking distance of established power houses is ideal.

The central station manager and the farmer have different "angles of attack," but in reality their interests are the same It takes time, however, to size up correctly a new situation of this kind, and this fact accounts for the tardy development of electrical matters in rural districts.

The successful farmer of to-day is vastly different from the farmer of a generation ago. He operates, maintains and develops his farm with the care and shrewdness of a business man. He analyses his soil with the sole purpose of determining or of adapting to it the kind of crops best adapted to its characteristics and conditions.

He realizes that his stock must no longer trample tons of fodder under foot during the feeding season. Instead, he must cut the roughage and feed it in such manner that there will be little waste. The result of adopting such an obviously better method is success.

All this, however, takes power, and the old time tread mill is too awkward to harmonize with the situation under the improved conditions. Power machinery, therefore, becomes a necessity, and the electric motor is ever the dream of the man who wishes to be abreast of the times.

The matter of finance has yet to be mastered by most farmers, and central station men must remember this when arranging for the farmer's initial investment It will be policy to find a way to provide the line wires, transformers and meters, but cutting and hauling poles is a farmer's work and one can well leave this to him. He is often a skilful mechanician, familiar with the technique of a trade, and he or his sons take just as kindly to the handling of a dynamo or motor as they do to the operation of an automobile The main thing to do in introducing electrical applications on the farm is to utilize—not in the city but on the spot—all these latent possibilities.

A New System of Bunkering Steamships

The "Herald" and Her Performances

By F. C. Coleman

ONE of the latest developments in the bunkering of steamers is represented in the "Herald," a twin-screw coaling vessel shown in the photographs The "Herald" is fitted on the Holland-Johnston system with two elevators, and has a speed through the water of 6 knots The capacity of the vessel is 400 tons of coal, and the output 100 tons per hour per elevator i. e, 200 tons per hour for the vessel Our frontispiece shows the "Herald" bunkering the London & North-Western Railway Company's mail steamer "Anglia" and gives a clear idea of the construction of the vessel The coal is carried in pockets or compartments on each side of the vessel Between the compartments and extending nearly from one end of the coaler to the other, is a longitudinal passage up and down which the movable elevators are free to travel The system is novel and differs from other coaling methods inasmuch as though the "Herald" has only two elevators, larger vessels fitted in the same way might have three, four or five elevators, and with each of these elevators having an output of 100 tons per hour, it would be possible for a vessel so fitted to discharge herself at the rate of 500 tons per hour Large ocean liners served by large vessels of the "Herald" type, one on either side of the liner, such as the "Mauretania" or "Lusitania" and the big vessels of the White Star Line, could thus be coaled at the rate of 1,000 tons per hour

A thousand tons per hour may appear a very large quantity of coal to transfer from barge to steamer, and it can only be done by a system such as that on which the "Herald" is constructed, because to attempt to pass that quantity of coal down one shoot, or even two shoots, would mean that the discharge would have to be so rapid that the delivery of it could not properly be taken In the "Herald" system, however, different shoots are put through the side bunker doors in different parts of the vessel and coaling is thus going on simultaneously in practically all parts of the vessel's bunkers, consequently, the only delay with this method will be at the final trimming in the top of the bunkers, which must always be a slow operation

The elevators may be moved from any one point in the trunk to another, being carried by the trucks on rails, which are shown in the photographs In addition to this flexibility of the positions of the elevators, the barge itself can, of course, be moved, consequently there is no doubt that any vessel with side bunker doors may be coaled by this design of plant

When supplying coal to vessels provided with center bunker hatches instead of shoots, conveyors are put into operation for the purpose With other systems of coaling a great drawback is experienced with the fine coal dust or dirt which gets blown about by the wind and covers the vessel being coaled from end to end with dirt Compare these systems with the method of loading the London & North-Western Railway Company's mail steamer "Anglia," by the "Herald," and it will be seen that the complete absence of dust in the case is remarkable. Coaling by means of the "Herald" is a very clean operation No dust whatever gets on board the vessel being coaled.

The elevators are driven by a very ingenious multiple gear in the top pentagon drum, the small engine necessary for the purpose being contained at the head of the elevator between the top and the bottom trunks The exhaust steam from this engine is admitted into the head of the elevator in a suitable position, and is directed along the shoots into the vessel's bunker doors. The illustration shows the steam It was found by experience that coal dust is carried straight into the vessel's bunkers with the steam, thus insuring an extremely clean method of coaling steamers. It is stated that the steam does not in any way wet the coal.

With two elevators, the crew of the "Herald" consists of the master, the engineer, the assistant engineer, a fireman and three deck hands. This crew is sufficient to navigate her and do all that is necessary in connection with the bunkering of steamers. The salient features claimed for this bunkering system are: Flexibility as regards the shoots, cleanliness, rapidity and economy.

The Brooks Comet

By Prof. W. R. Brooks

THE new comet discovered in July by Dr. William R. Brooks, director of the Smith Observatory, Geneva, N Y., is now visible to the naked eye, and in a very favorable position for observation on the western side of Pegasus. The comet has moved up through the northern part of Cygnus, and on September 10th was about 20 degrees northwest of Vega, the brilliant star in the constellation Lyra, and now overhead in the early evening This was its greatest north declination, about 57 degrees From this place the comet is moving first westerly, then southwesterly as it speeds toward the sun.

The following ephemeris will show the comet's track through the northwestern heavens. Those not having telescopes with graduated circles, can plot these positions upon a good star atlas, and thus get the comet's relative place to the well marked stars in its course:

September.	R. A.	N Declination.
13	17 hrs. 10 min.	+57 deg 9 min.
17	16 " 18 "	55 " 42 "
21	15 " 31 "	53 " 90 "
25	14 " 51 "	49 " 21 "
29	14 " 17 "	44 " 56 "
October.		
3	13 " 49 "	40 " 6 "
7	13 " 26 "	34 " 51 "

The comet was nearest the earth on September 17th, when its distance was 45,000,000 miles. While the comet is visible to the naked eye, an opera or field glass will add to the pleasure of the observation.

Correspondence

Octave Chanute and H. T. Ricketts—A Sidelight

To the Editor of the SCIENTIFIC AMERICAN:

The very appreciative article on Octave Chanute by Prof. Zahm, in your issue of May 13th, recalls an interesting coincidence occurring not far from the commencement of certain close relations between the writer and Mr. Chanute during the last eighteen years of his life.

One morning in the early summer of 1896 Mr. Chanute inquired, somewhat quizzically, but in his usual serious and methodical manner, as to a young doctor who might not be too busy or too dignified to accompany him—for a consideration—on an expedition where he, the doctor, would be expected to do cooking during the few spare moments when he was not engaged in the professional duty of setting broken limbs.

This inquiry was typical of Mr. Chanute's customary way of launching an enterprise—foresightedness, economy of service, shrewd calculation of adequate margins of safety, were but outcomes of his instinct and distinguished training as a bridge engineer. Having tried out his air planes and kites among the tin cans and sand lots at the foot of Huron Street, he was preparing for his gliding experiments at Dune Park, Ind. With the fate of Otto Lilienthal fresh in his mind, he did not propose to let the members of his little company smash their bones without having some representative of the coroner available. It was a part of his spirit of cautious frugality that had he been spiritually minded he would have proceeded just as methodically to secure the services of a chaplain willing to take on a side line of washing while waiting for emergencies.

I knew Mr Chanute too well not to receive his request in the same spirit of courtly gravity in which it was made. And here is where the coincidence came in—I sent with him a solemn-faced conscientious student of medicine then helping me in my office, who was as single-minded a crusader in his own sphere of science as was Octave Chanute in his. What Howard Ricketts did not know about cooking, his temporary employer—a Frenchman and an epicure—informed me, would have filled a large Creole cook book, and as a surgeon he never had a tryout on Herring's or Avery's legs. But looked up even then in my young friend's breast was the purest, most deeply religious and unselfish love of science with which I have ever been privileged to come into intimate contact. Ricketts had no money, he cared nothing for it except as a means toward achieving his ambition to become an independent thinker in the sphere of pathological biology. He sat up nights with his ideas until his health was ruined, and his friends began to think him obsessed; perhaps he was a little so on commonplace subjects, but it was the obsession of preoccupation with connected thought, a form of mental peculiarity uncommon enough to seem queer to most of us, who are willing—*post hoc*—to admit that genius is usually a form of successful queerness.

Curious, was it not, that the lives of these two great serious and clean-minded scientists should have touched thus semi-comically and casually, only to drift presently apart again without influence upon or understanding of each other. Ricketts always thought "flying" was the one really jocular event of his life, and expected to eventually hear of his patron's incarceration for too lavish expenditure of money on box kites. Mr. Chanute associated Ricketts with nothing but spoiled meals, and pursued the disagreeable subject no farther—of what use was biology to the mathematician? And so each of these productive nineteenth century materialists thought the other a hopeless, useless visionary!

Yet Ricketts, like Chanute, "dreamed true," and his brief life with its tragic end—a last willing offering to his great goddess—was crowded full of those undramatisable epics of the modern laboratory that recall to us, if we have but the logical imagination to see them in their true stature, the heroic lives of early explorers, patriots, or religious enthusiasts. Pasteur and *Metschnikoff* gave him of their inspiration and technique. Animated by their methods, he struck out into new-world fields and returned with or finally sent back fresh contributions to science, destined also to prove of inestimable practical value to humanity. His original studies in pathological biology have never been equaled on this continent. His discoveries in blastomycosis gave him early recognition, and won for him an appointment at the University of Chicago. He spent three years studying the hitherto mysterious "tick fever" of the Rocky Mountains, and placed its etiology and pathology on a firm foundation. His experimental work in the immunity of organs received world-wide recognition and won for him in 1910, when barely thirty-eight years of age, the appointment to the chair of pathology at the University of Pennsylvania. As an especial mark of honor, the appointment carried with it a year's preliminary *freedom* for research work *at a full salary*, before entering upon active teaching service. As his final tribute to science he gave his life at its meridian in exchange for a knowledge of the secret sources of Mexican typhus. But not before that knowledge had matured from theory into fact, and the life history of the *micro-organism of the disease* lay *unfolded* before him under the microscope and in the culture medium. The Mexican government co-operated liberally with him during his work, and since his death in 1910 has given him unstinted recognition in an appreciative state paper transmitting his records to this country. We have now for the first time a complete biological and morphological history of the bacillus of typhus fever—a filth disease transmitted from human to human through the *intervention of the body louse* as an intermediate host. These records, with others of importance made by the same hand, have just been edited and published for the University of Chicago* and the Chicago Pathological Society.

It is not difficult for one who knew both of these natures well to see why they repelled and misunderstood each other. Their method in dealing with and their mental attitude toward, facts were from opposite poles. Ricketts's method was intuitive and highly imaginative—an old-fashioned dreamer working backward from theories and ideals to facts. He saw the truth correctly but intuitively, the facts came inevitably but later. Chanute collected facts during a lifetime of mature and precise mathematical thinking, and by methods of pure induction arrived step by step at correctly demonstrated conclusions, eventually beyond even the insane dreams of Darius Green. And yet he also was an unselfish idealist, as is abundantly evidenced by his refusal to accept the commercial advantages which his basic patent on the biplane undoubtedly gave him. The several hundreds of unpublished letters, full of technical details and mathematical calculations, which passed between him and the Wright brothers, and which are now in the possession of the Chanute estate, would indicate that his interest and his equity in the machine-driven biplane, while not at all tainted with commercialism, were vastly more than passing and casual. The reported saying that he "turned up" or "happened to drop in" at Dayton or Kittyhawk in 1901 cut him deeply and was scant recognition when viewed in the light of this unique and instructive correspondence between two great scientific men. The secret of this interest is an open one to those who know the mainsprings of his life and character. That secret, after his modest fortune was acquired, was an abstract and impersonal devotion—incapable of jealousy—to the pursuits and achievements of pure science as apart from material gain and advancement. A motive power common enough in the old world, and still more so under the *ancien regime*—the day of Newton and Franklin, of Laplace and Priestly, of Humboldt and Goethe but not commonly to be reckoned with amid the commercialism of present-day American life.

In the midst of and a recognized factor in contemporary supply and demand of modern railroad necessities, he still preserved unchanged the manner and family life of the French gentleman of the eighteenth century. Refinement, honesty, idealism, gentleness, all were his; yet he was full of fire in manner, spirit and inspiration. He was modest, yet he knew and gave himself his full value and dignity, as many of his letters abundantly show. In his seventy-ninth year his keen eyes sparkled like a boy's, and his wit was still as caustic as Montaigne's. On his death bed he corrected letters and telegrams with an enjoyment in the ultimate refinement of words that was altogether French. A many-sided nature in which were joined the pure philosophic altruism of the eighteenth century with the keen love for productive mathematics of the most modern American.

An early competence was won by strict business methods; then followed "retired leisure that in trim gardens takes its pleasure," only the gardens were the Illinois and Indiana sand dunes, and the leisure was an industrious but impersonal life in the fourth floor of a city house, surrounded by models and stuffed winged creatures and an abundant library of mathematical and engineering literature. The product of these voluntary labors, which he gave unselfishly to the world, showed as a net resultant all that was correct winnowed by patient experiment from a thousand ventures incorrect in their entirety. The Chanute biplane model, in its simplicity of line and principle, is a type of all those products of matured "genius" which are really the resultants of skillful elimination of the unnecessary and illusory. The accident of bodily age prevented personal flight. The accident of five years' delay in the development of the gasoline motor alone prevented the complete equipment of an otherwise perfect model.

It has been among the great privileges of my professional life to have had intimate contact with and to have formed an early appreciation of the value of these two great lives—lives so unlike in the details of their working out and surroundings, and yet so fundamentally similar in devotion to abstract science and in the altruistic determination to give largely and unselfishly that humanity might be the gainer.

Why Left-hand Mold-board Plows are Used

To the Editor of the SCIENTIFIC AMERICAN:

The following might be of interest to you in regard to the short article about mold boards for plows in the SCIENTIFIC AMERICAN of June 17th, page 603.

As far as the work done by the plow is concerned, there is, of course, no difference between a left hand and a right hand mold-board plow. The choice between the two depends, however, on the manner in which the team (two horses or mules) is driven or guided. If a *single* line is used, it is customary to connect it to the left (lead) horse, in which case the team is entirely led by this horse and by one line (*single* connection between the left horse and driver).

After the first furrow has been made, it in itself is the best guide for the team, and since the second horse (right hand horse as seen from the plow) is entirely guided by the "lead" horse the latter should walk in the furrow. This arrangement however, is possible only with a *left hand* mold board plow.

With one horse plows, or when the team is driven by a double line, it makes theoretically no difference whatever whether the plow has a left hand mold-board or a right hand mold-board.

Washington, D. C. F. A. WELBY.

Who Saw This Meteor Train?

To the Editor of the SCIENTIFIC AMERICAN:

On the night of September 4th, I noticed extending across the heavens at New City, N. Y. what I think must have been a "persistent meteor train" as recently described in the SCIENTIFIC AMERICAN. It first attracted my attention at about ten minutes past eight and was then in the northern sky in the form of a large circular arc not unlike a rainbow, but of much greater radius of curvature and extending almost completely across the sky from west to east.

The train drifted rather rapidly in a southerly direction and apparently straightened out as it reached the zenith, remaining perfectly straight until it was lost to view at a few minutes after nine.

The atmosphere was perfectly clear, the sky absolutely cloudless and the moon nearly full, shone brightly in the southern sky. At first I thought it was a peculiar cloud formation but it apparently had a luminosity of its own and someone remarked to me that, "It looks like the stuff of which the aurora borealis is made." Stars were plainly visible through the luminous mist and as it crossed the Square of Pegasus I noticed that it was almost as wide as the square, its length I estimated was 135 degrees or over.

As the streak crossed the moon's disk the section in front of the moon was made invisible by the bright light but on each side the segments were still plainly visible although considerably narrower than when at first observed and still in a straight line.

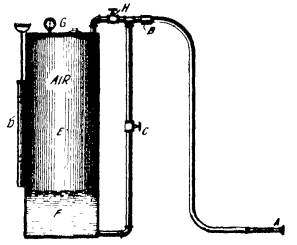
I would be very much interested to know whether this peculiar luminous streak was seen by other persons and whether it has been reported by anyone who knows what it was. EDGAR PEARCE.

New York.

The National Tree of China

THE tung, or wood oil, tree is worthily named the national tree of China. It is stately in appearance, with smooth green bark and wide-spreading branches, affording a fine shade. It bears a fruit resembling a shell bark hickory nut, but as large as a small orange. Each nut contains three triangular seeds similar to small Brazil nuts. The oil is pressed from these seeds, and the refuse is used as a fertilizer. The oil is used principally for polishing wood work and dressing leather. Considerable quantities are exported.

The wood of the tung tree is used for making musical instruments, fine boxes and the framework of small houses. It is believed that this tree might flourish in warmer parts of the United States.



Suggestions for the Workshop

Ingenious Expedients of Resourceful Mechanics

Gasoline and Compressed Air for Cleaning

By J. E. N.

It is a common practice in automobile shops to use gasoline and compressed air to clean the dirt from otherwise inaccessible parts of an automobile, the apparatus employed requires a specially made nozzle connected with a double line of hose. The apparatus illustrated in the accompanying engraving, which was made by a friend of the writer, accomplishes practically the same result in a simpler manner. It consists of a galvanized tank *E* provided with a tube, soldered into it at the top, and another one at the bottom. These tubes are fitted with valves shown at *C* and *H*. The tubes are joined and are connected by means of a ¾ inch hose *B* of any suitable length, say twenty feet, to a nozzle *A*. The nozzle should be provided with a quarter-inch aperture and a flared outlet. A bicycle pump *D* is connected with the tank

Gasoline and air tank for cleaning automobiles.

at one side and a pressure gage *G* is secured to the top. In use, a gallon of gasoline is poured into the tank, as indicated at *F*, and then the pump is operated to produce a pressure of several pounds in the tank. The valves *C* and *H* may now be opened to such an extent as to permit a small quantity of gasoline and a comparatively large quantity of air to flow though the hose and the nozzle *A* may be directed to spray the parts which need cleaning. A single gallon of gasoline and a few strokes of the air pump have been found sufficient to clean thoroughly a single automobile. This type of apparatus cannot compete in efficiency with that used in automobile shops, but it is a practical device for a private garage.

How to Make an Engine Crank

By Albert F. Bishop

The task of making an engine crank is by no means beyond the abilities of the average amateur mechanic. The following directions will be found comparatively simple.

Take a piece of steel 2 inches thick, 5 inches wide and of a length to suit the purpose. A thin paste made of chalk dust and water may be spread over the metal and when dry it will provide an excellent surface for taking the lines of a sharp lead pencil. The crank may be laid out on this surface to the exact size required. The lines indicated in the accompanying

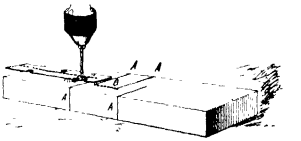


Fig. 1.—Cutting out a crank shaft.

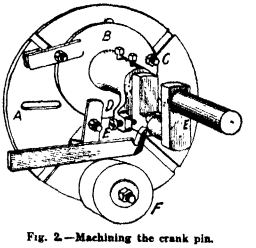
drawing at *A* (Fig. 1) can be cut with a power saw. The cuts running lengthwise of the piece can be made to better advantage by drilling, although the two long cuts might be made by the power band saw. To facilitate the operation of drilling, a jig should be made of cold rolled steel 1/16 inch thick, 2 inches wide and about a foot in length. Drill holes in this piece in a perfectly straight line, spacing the holes as close together as possible without letting one cut into the other. This jig need not be hardened unless a large number of cranks are to be drilled. The piece should be attached to the surface of the steel plate by means of three machine screws. Now, the workman can proceed with his drilling and if the holes have been laid out nicely in the jig, the steel can be separated without much trouble after drilling.

After the crank has been cut out roughly in this manner it may be centered on the ends and turned in the lathe. The tool should be sharpened with considerable bevel and made to cut deep but thin chips, taking off nearly the whole corner at the first cut. This procedure will do away with a great deal of knocking. The cranked shaft should be roughed out at first, leaving plenty of stock for the finishing cut. For turning the crank pin, make a flange of the form indicated at *B* (Fig. 2) with two ears at the outer end, as shown at *D*. The machining on this casting is simple. It consists in facing the flange and boring it out to receive the crankshaft. The flange is clamped to the face plate and a bolt at *C* acts as a pivot, so that adjustment up or down can be secured by tapping the piece lightly with a hammer. The straps are then bolted securely. Lateral adjustment is attained with two set screws indicated at *E*. Two more set screws will serve to hold the shaft firmly in the neck of the flange. A counterbalance *F* may be strapped or bolted to the face plate.



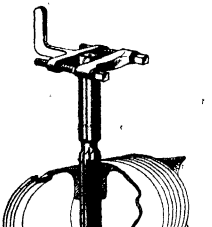


Fig. 2.—Machining the crank pin.

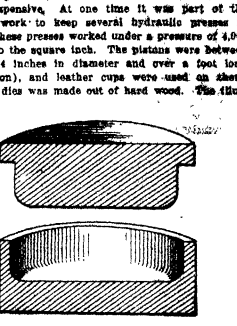
Enlarging a Reamed Hole

By R. P. Albert

When a mechanic desires to enlarge by several thousandths of an inch a hole which has already been reamed with a standard reamer, he can readily do so by wrapping paper around the tool, covering about three-quarters of its circumference and



Enlarging a reamed hole.

leaving several cutting edges bare. The paper should be carried around with the reamer when the tool is in use. Graphite or the lead of a pencil should be rubbed on the outer surface of the paper to serve as a lubricant when the reamer is rotated.

A Leather Cup Die

By J. E. Noble

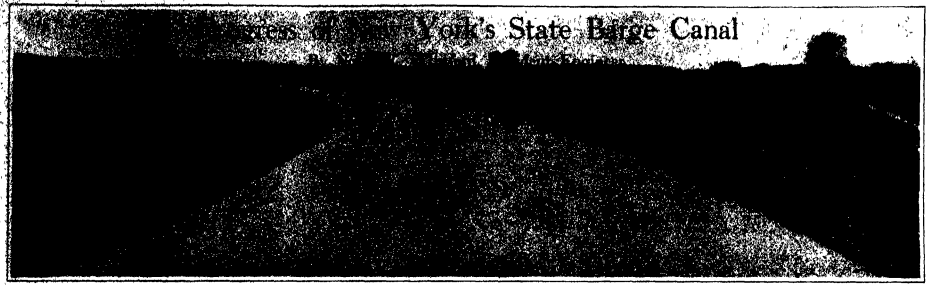
Men who have much work to do around hydraulic presses know how annoying it is to find they are out of cup leathers just when they are in a hurry for one. The price charged for cup leathers by some dealers is out of all proportion to the material that is in the cup and the labor required to turn them out. The iron dies generally used to make cup leathers are also rather expensive. At one time it was part of the writer's work to keep several hydraulic presses in order. These presses worked under a pressure of 4,000 pounds to the square inch. The pistons were between 12 and 14 inches in diameter and over a foot long (solid iron), and leather cups were used on them. A set of dies was made out of hard wood. The illustration shows a sectional view of them. They were turned out on a lathe. The concave part was turned out to the size of the cylinder in which the piston worked, and the convex part was turned down to a diameter one-half inch smaller. The leather was cut to a diameter twice that of the piston plus twice the depth of the depression in the die. It was moistened in tepid water for a few minutes, and then pressed in the dies. With a heavy weight to provide the necessary compression the leather was left for several hours. A single pair of dies was used for two years, at the end of which time they were apparently as good as ever.

Wooden dies for cup leathers.

Combination Pipe and Monkey Wrench

A common monkey wrench may easily be adapted for use as a pipe wrench for emergency work, thus making it unnecessary to carry two wrenches in the tool kit. Take an ordinary monkey wrench and mill a small groove in the fixed jaw, as shown at *A*. This groove should be milled on a taper as shown.

When the wrench is to be used on a pipe, take an old piece of bolt or stud, harden the threaded parts and place the stud in the groove that has been milled in the jaw of the wrench. This will prevent the wrench from slipping around the pipe while in use.



A monkey wrench used as a pipe wrench.

Workshop Notes

How to Weld Cast-Iron.—A good compound for welding cast iron is made as follows: 41½ parts boracic acid, 35 parts common salt, 20 parts ferrocyanide of potassium, 7 parts resin, 3 parts carbonate of sodium. Heat the metal to a light-red heat and apply the mixture over the part that is to be welded. Then heat to a yellow heat, and the welding may be done in the usual manner.—H. D. Chapman.

Novel Method of Removing Broken Ax Handles.—A recent issue of Handy Man's Workshop contained a suggestion on removing a broken handle from an ax head. I think it can be done more conveniently in another way. When I break a handle, I fasten the tool head in a stump or some other place, take my shotgun and put the barrel about 2 or 3 inches from the plug in the ax. The trigger is then pulled, and no matter how hard the handle was fastened, it has to come. There is no danger that the shot will be reflected back to the gunner, even though it strikes the ax head.—H. T. Peterson.

Progress of New York's State Barge Canal

WHENEVER the administrative heads of great enterprises change, the general public renews for a time its interest in the undertakings intrusted to their care, and when these enterprises have a national importance, the interest is intensified. So it is now with the New York State Barge Canal.

At the beginning of the year the incoming State Engineer found construction work on the barge canal improvement about one-third completed and contracts in force covering 96 per cent of the total mileage. He also found that, although most of the work was under contract, many of the contractors had been extremely dilatory, some of them having done very little, notwithstanding the fact that considerable time had elapsed since the award of their contracts. One feature in particular was found to be backward, a feature most essential to the completion of the project, namely, agreements with railway companies whose lines cross the canal, whereby the necessary bridges may be built or changes made.

As the general characteristics of the barge canal—its route, dimensions, number and kind of structures, capacity, cost and the like—have often been told before, they need not now be repeated. Rather it seems preferable to describe briefly some of the special features. By supplementing these descriptions with views of completed sections of the canal and other views of great structures under construction, or interesting bits of detail, a general idea of the undertaking should be conveyed.

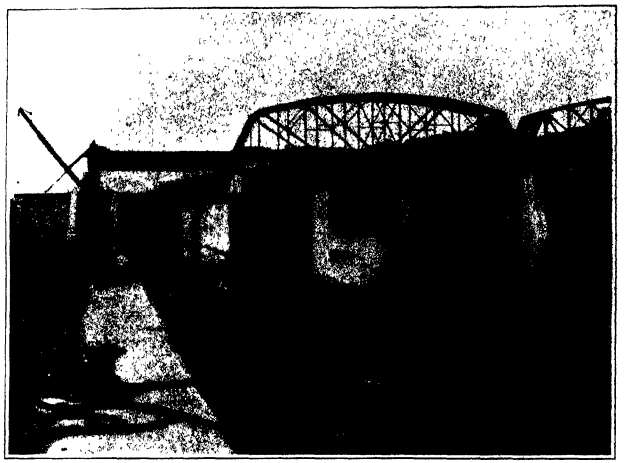
At the opening of navigation last spring several of the new locks were so nearly completed that they were put in commission and have been in use during the past season. To maintain navigation on the existing canals, it has been necessary at certain localities to turn traffic into the new channels as soon as they were ready. Such a case has occurred at Oswego, where the canal enters Lake Ontario, and the lock at this junction is, perhaps, the most interesting of any along the whole line, for it is the first siphon lock to be built in this country and also the largest lock to which the siphon principle has ever been applied.

All of the locks on the canal are filled and emptied through culverts in the side walls, these culverts communicating with the lock chamber by means of lateral openings, termed ports. In all of the locks except the one at Oswego the flow through the culverts is regulated by gates, sliding vertically. In this lock, however, the culvert is curved and forms a neck above the top of the wall. To start the flow in this neck it is only necessary to exhaust the air; to stop the water needs but the readmission of air—a simple application of the well-known siphon principle. The interesting part in the device for creating a vacuum. This is a tank built in the wall and communicating by pipes with the upper and lower pools and by an air pipe with the top of the siphon. By filling this tank with water, then closing the upper pipes and opening the lower one, there is produced in the tank the effect of a body of suspended water tending to escape into the lower pool, thus creating the vacuum necessary for operation. The opening of a valve admits air from the siphon to fill this vacuum, and this exhaustion of the air starts the flow of water through the culvert. At a certain stage the rushing water carries the remaining air along with itself and reverses the action of the tank, drawing back the air and reforming the vacuum, ready for the next operation.

The pipe for filling the vacuum tank is 12 inches in diameter, while the outlet measures 20 inches and the air pipe 4 inches. It readily appears, therefore, that all of these valves may be manipulated easily by hand, especially since the regulation of the 4-inch valves is all that is required, unless the leakage of air necessitates the refilling of the tank. This simplicity and economy of operation and of maintenance and the absence of steel work under water to deteriorate by rusting, together with a less cost for construction at this particular location at least, are the features that recommended this type of lock. Its use during the past season has not been disappointing. Two siphon locks are now being designed for the recently authorized addition to the barge canal system—the Cayuga and Seneca canal. The type appeared first in 1896 on a canal in Northern Germany, and since then others have been built at a few places in Germany, but it has characteristics that doubtless will commend it to an increasing use.

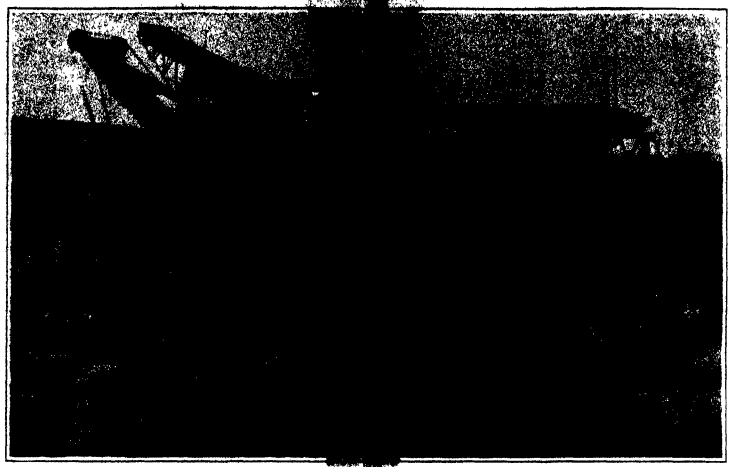
A movable dam of the bridge type

There is another novel type of structure that has recently been built on the canal, having been originated in its design, and this also employs the siphon principle. It happens that at certain places there are at times considerable quantities of surplus water that must be disposed of rapidly and yet the surface must not be lowered below a given point. To do this without the use of regulating gates and the accompanying cost of attendance, it is necessary to have some automatic device usually a simple spillway with its crest at the required surface elevation. But cases have arisen on the canal at certain points where there was not room to place a spillway of sufficient length to pass the surplus. Hence the new type—designated a "siphon spillway." It consists of a concrete wall in which are left openings in the form of siphons. The intake is several feet below the surface of the body of water that is to be regulated, while the elevation of the outlet is governed by the depth of the stream into which the surplus is spilled and the bottom of the neck reaches to the elevation at which the water surface must be maintained. As the neck is flattened to the form of a broad, low rectangle with its top at the elevation to which the water may rise before discharge is to begin, the siphon is full when this point is reached, the air having been driven out by the water, and the siphon action becomes automatic. Air vents pierce the upper side of the wall at low water surface and thus the stoppage of the flow is also automatic. A short spillway or drift gap, to carry off floating debris completes the structure. Two of these have been built and successfully operated.



There are certain structures that have been in course of building on the lower Mohawk River for some two years but not until recently have the outlines of their peculiar features become manifest to others than those immediately concerned. These structures are the locks and dams that are located at eight places between Schenectady and Little Falls. The peculiar features are embodied in the dams, for they are movable dams of the bridge type—the first to be built in this country. In constructing them it was necessary first to build abutments and piers, the same as for an ordinary bridge, and also to place a broad concrete sill in the bed of the river extending between abutment and pier. After these operations, a bridge superstructure was thrown across and then the distinguishing features were added—fabricated steel beams suspended in pairs 15 feet apart and reaching from the bridge to the concrete sill. Upon these frames were then placed gates, of heavy steel plate fitted with rollers for sliding on the uprights.

For convenience in regulating the stream the gates are divided horizontally in two tiers. When they are closed and the structure is in operation as a dam, the bottoms of the lower gates will rest on the concrete sill and the tops of the upper series will form the crest of the dam to govern the elevation of the water surface at ordinary stages. Whenever it is desired to permit the escape of more water than will spill over the crest the gates are partially raised, one or all, and the water passes through the aperture thus provided. In time of extreme flood or during the winter season both gates and frames may be entirely removed from the stream, leaving an unobstructed channel. To accomplish this the frames are attached to the bridge by a hinge-like joint, so that they may be swung up under the bridge floor to a horizontal position, carrying the gates with them. Steam winches, moving on tracks on the bridge floor, wind or unwind chain cables, to perform all of the work of operation.



A spectacular feature attending the building of the Barge Canal is a change in the map of the State that will add to its lakes two bodies of water of considerable size. These will impound a needed water supply, and are known at present on the plans as Delta and Hinckley reservoirs.

A profile of the canal across the State shows a continuous descent from Lake Erie to the confluence of Seneca and Oneida rivers, then a rise to the con-

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

Sir William Ramsay's British Association Address

THE presidential address delivered by Sir William Ramsay before the meeting of the British Association for the Advancement of Science at Portsmouth was a novelty in its distinguished position, for it was discursive. In the opinion of the *London Lancet*, "Sir William Ramsay delivered an address which was generally retrospective, seeking to picture the present position of civilized nations politically, scientifically, socially, educationally, industrially, imperially, in contrast with periods of the past."

The *Lancet* regards as the most remarkable passages in his address those in which he referred to the position of the elements of radium and the wonderful manifestations of its energy. "From its physical and chemical properties radium is an undoubted element, but, as Sir William Ramsay observed, it is a very curious one, for it is unstable, and hitherto stability has been believed to be the essential characteristic of an element. Radium, however, disintegrates—changes, that is to say, into other bodies, and at a constant rate. If one gramme is kept for 1,760 years only half a gramme will be left at the end of that time, half of it will have given off other products. It yields a condensable gas—radium emanation—and besides evolves helium. Helium seems to be a veritable element, and radium emanation has been shown to be incapable of chemical union, but it has been liquefied and solidified in the laboratory of University College, London, and its spectrum has been measured and its density determined. The emanation has been called niton to recall its connection with its congeners, argon neon, krypton, xenon helium and its phosphorescent properties. The atomic weight of niton is 222·4 and that of helium 4. The sum 226·4 is the atomic weight of the parent radium. But the descent does not stop there. Niton in its turn gives radium A and helium, radium A rapidly gives another solid substance, radium B, helium again accompanying the change. Soon a half of B gives place to radium C, but in this case no helium is evolved, only atoms of electricity to which the name "electrons" has been given by Dr Johnstone Stoney. Radium C has a short life, for it changes into radium C', parting with helium atoms. In two and a half minutes, however, radium C' is half gone, parting once again with electrons and forming radium D, which is longer lived, its disappearance eventuating in radium E with apparently no discharge of electrons or helium. Radium E changes spontaneously into radium F, which is the substance to which Madame Curie gave the name 'polonium.' In 140 days, however, polonium in its turn is half changed into an unknown metal, supposed to be possibly lead. Then apparently a check to the rapid descent takes place, for lead within present human limitations, at any rate, is stable.

"But there is no reason why even the stable elements should not decompose when subjected to enormous strains. The virtue of the energy of radium consists, as Sir William Ramsay pointed out, in the small weight in which it is contained, energy here is in an enormously concentrated form. It is disappointing to be told, therefore, that the supply is a very limited one, and that it can safely be affirmed that the production will never surpass half an ounce in any year. The small quantities, however, which have been so far produced have afforded sufficient energy to induce the degradation of elements hitherto regarded as stable. The action of niton or radium emanation on salts of copper appears to show that the metal copper can be converted partially into lithium, and similar experiments indicate that thorium, zirconium titanium, and silicon are degraded into carbon, for solutions of compounds of these, mixed with niton, invariably generate carbon dioxide, while cerium, silver, mercury and some other metals give none. This is all a very wonderful story, and we may well ponder over the possibilities for the human race to which these discoveries are leading. Sir William Ramsay suggests that if elements are capable of disintegration, the world will have at its disposal a hitherto unsuspected source of energy. If radium were to evolve its stored up energy at the same rate that gun-cotton does, we should have an undreamt-of explosive, could we control the rate, we should have a useful and potent source of energy provided always that a supply of radium were forthcoming. If, however, the elements which we have been used to consider as permanent are capable of changing with evolution of energy, if some form of catalyzer could be discovered which would usefully increase their almost inconceivably slow rate of change, then it is not too much to say that the whole future of our race would be altered;' that is how Sir William Ramsay pithily sums up the position. A fuller account of his address will be found in this week's SUPPLEMENT.

Use of Cement Gun by the Government

THE "cement gun," a device for putting concrete in place by compressed air, is being used by the Quartermaster's Department, United States Army, in the Hawaiian Islands, and is proving of value in the construction of the ordnance shop at Fort Ruger. The apparatus was originally provided with a nozzle that became worn and clogged easily. These difficulties were overcome when Capt. Edwards, quartermaster, invented a rubber lined nozzle that gave complete satisfaction. The following description of the device as used in Hawaii is furnished by Capt. A. B. Putnam, Corps of Engineers:

The cement gun is manufactured by a New York company, and consists of an air compressor, a 4-cylinder marine gasoline engine of 20 horse-power, a 1 inch wire-wound rubber hose with walls three-eighths inch thick for delivering dry sand and cement mixed, an ordinary garden hose for delivering water to the nozzle of the gun, and the gun or nozzle itself.

The nozzles originally furnished with the machine were not rubber lined and soon became abraded, so as to render them worthless. The nozzle used by Capt. Edwards, quartermaster, is lined with rubber (about three-sixteenths inch), so that no mortar sticks within. Furthermore, the rubber lining does not appear to become worn under use except very slowly.

A mixture (1 to 2½) of cement and fine sand is delivered to the nozzle at 30 pounds pressure, and just before being discharged is met by a circular spray of water at 30 pounds pressure within the nozzle, so that the wet mortar is projected on the surface to be covered. The water supply is regulated at the nozzle to obtain the correct consistency.

Triangular mesh is secured by staples to the studding of the structure, and is backed up by either heavy paper or wood placed so that the mesh will be in the center of a mass of stucco 1¼ inches in thickness when the spraying is completed. In dwelling houses the stucco is placed on the studding inside as well as outside, but is made only about three-fourths inch thick inside. Smoothing is done by shooting a fine light spray of wet mortar. No finishing is done with the trowel. The finished surface inside is to be painted. The resulting stucco is very hard and makes a fair appearance, though it is necessarily rough. So far, provided the mesh is placed so that edges overlap, I have observed no cracking. It should be noted that this stucco is merely a thin wall of plaster, and bears no strain except that due to its own weight.

When stucco is placed inside and outside, the paper backing (10 pounds per 100 square feet) is left in the wall. When only on outside is placed, the wood or paper backing is removed when the stucco has hardened.

At this date of writing one gun is placing 90 square yards, 1¼ inches thick, per working day. The cost at present, including cost of studding and backing in place, is $1.13 per square yard.

The hose now in use is stronger and heavier than the one supplied with the outfit, and the nozzle is different, being about 12 inches long, as against about 4 inches as supplied, and being rubber lined throughout, so that the mixture never touches metal. There has been but little work done here as yet, so that cost data are not complete, and it has only been since Capt. Edwards applied a new nozzle that the gun worked well.

Tests are to be made by the Isthmian Canal Commission to determine the value of cement mortar, applied to iron plates by the "cement gun," as a preservative of iron at Panama. Twelve plates, 63.8 by 14 inches, have been coated with a 1 to 3 mortar of cement and sand, after they were cleaned to gray metal by the sand-blast process. Six of these have been covered with a ½-inch coating, and the remaining six with a 1-inch coat on one side, and a 1½-inch coat on the other. Three plates of each kind have been sent to Balboa, and three to Cristobal, where they will be kept immersed in salt water to test the mortar method of preventing corrosion. Two plates of each kind will be taken from the salt-water bath at the end of three months, and one-half of the coating will be removed to determine the condition of the metal. The duration of the test for the balance of the plates will be determined later.

Aviation in Japan

IN the *Deutsche Zeitschrift für Luftschiffahrt* Dr. Demcker reviews the history of aviation in Japan. Although the art of making kites has been cultivated in that country from time immemorial, and the man-lifting kite—the precursor of the modern aeroplane—was, according to tradition, utilized by a banished daimio to send a message to his vassals in the year 1156, Japan has been slow in taking a share in the great recent development of aviation, as well as of other branches of aeronautics.

Two years ago, however, the Japanese government sent two army officers to Europe to study aviation, viz., Capt. Hino to Germany, and Capt. Tokugawa to France. These officers, besides making themselves proficient in the art of flying, purchased on behalf of their government a number of aeroplanes of various makes—Blériot, Wright, Grade, Farman—and have now returned to Japan, where they are giving instruction to a number of other officers. For the purpose of these lessons the government has established a large aviation field about two hours' journey by railway from Tokyo.

The government has also organized an official society for the study of aviation, its members all being government employees, including military and naval officers and professors in the imperial university. A grant of $375,000 has recently been voted to this organization.

The Japanese are not entirely dependent upon foreigners for their flying-machines. Capt. Hino, Dr. Narahara, Capt Isobe of the navy, Messrs. Morita and Tsutsuki, and Baron Iga have devised various forms of aeroplane.

Each of the important newspapers of Tokyo now has a department devoted to aeronautics. The *Hochi Shimbun*, the leading paper of the city, has engaged the services of Messrs. Takata and Inouye as "aviation editors," and the *Asahi Shimbun* has a similar functionary in the person of Mr. Usui. The semi-official journal *Kokumin* has offered a prize of $5,000 for a flight over the Bay of Tokyo.

"Stalloy"—An Iron Alloy of Peculiar Electrical and Magnetic Properties

PARTICULAR attention has been given to "Stalloy" by many investigators on account of the claims made by its inventor (Hatfield) with regard to its magnetic properties. A paper on this subject, embodying the results of a research carried on by H. R. Hamley and A. L. Rossiter, appears in a recent issue of the Proceedings of the Royal Society of Victoria. The principal facts and conclusions given by the authors are very briefly summarised below:

"The special feature of 'Stalloy' is its high specific electric resistance and high permeability. The specific resistance being about four times that of the best transformer iron, the eddy-current loss for a given thickness of sheet would be greatly reduced, so that lamination need not be carried out to anything like the extent necessary with ordinary iron, and the question of insulation of lamine becomes less troublesome. It is more expensive than ordinary iron, but the increased expense is compensated by a reduction in size of the transformers, etc., constructed of it, an increase in output, and greatly improved efficiency.

"The special chemical feature of 'Stalloy' is that it contains about 3.4 per cent silicon. The value of this alloy is emphasized in a paper by Epstein, where several tests of its properties are given.

"Several investigations have been made by other experimenters by direct current methods, which agree fairly well together.

"The object of the research was to investigate the magnetic properties of 'Stalloy,' not only with direct current, but also with alternating currents of varying frequencies.

"Summing up generally, it may be said that the chief results to be noticed are that—

"(1) 'Stalloy' cannot be used to advantage in the unannealed condition.

"(2) In the annealed state the results obtained fully bear out the claims made by the makers, the permeability being very high and the losses small, particularly the eddy-current loss.

"(3) The results slightly differ from those of other experimenters, the permeability being generally a little lower in our results than in theirs.

"(4) 'Stalloy' behaves very much like ordinary iron under varying frequencies.

"(5) The constancy of the value of the hysteresis loss for different frequencies is remarkable."

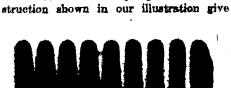
Oddities in Inventions



...vel Milk Bottle.—When unskimmed ... delivered to the consumers in the ... type of bottle, the cream forms a ... floating on the milk. In pouring ... the contents of the bottle they are ...essarily more or less disturbed and ...ingled. To provide a bottle that shall ...e free from this defect is the purpose of ...ecent patents here illustrated. The de...vice is extremely simple, resembling in ...general outline the customary milk bottle, ...from which it differs by having a lateral ...neck formed about the point where the

Milk bottle with a cream tap.

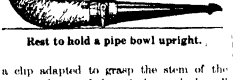
bottle reaches its largest diameter. Through this neck a curved tube of glass, paper or other suitable material is inserted, being free to slide in and out a certain distance, or to rotate about its axis. Both necks are closed with paper lids in the usual way. The operation of the device is so straightforward as to hardly require explanation. When it is desired to draw off the top layer of the cream the curved tube is turned with its inner end directed upward. If cream from a lower layer is required, the tube is turned accordingly. In transit, the tube is pushed in as far as it will go, to protect it against injury.

Tubular Springs.—Everyone is familiar with the fact that for a given weight a tubular rod has much greater rigidity than a solid bar, and the use of such tubular members in bicycles, automobiles and airships is a matter of common knowledge. No one, however, seems to have thought, until quite recently, of employing tubes in the construction of springs. A series of experiments carried out at the laboratory of Arts and Crafts (France) has shown that tubular springs of the construction shown in our illustration give

Tubular coil spring.

every satisfaction and possess many advantages, as is pointed out in "La France Automobile et Aerienne." As regards weight in particular, the economy gained varies somewhat according to the dimensions, ranging from about 40 to 60 per cent. But this is not by any means the only advantage. The smaller mass of the spring implies less inertia, with the result that the spring obeys more promptly the impulses which it receives. This is of importance where the spring is required to take up sudden jerks or rapid oscillations. Another effect of the small inertia of the spring is that an impulse communicated to one end of it is very rapidly propagated along its whole length, whereas in the case of a massive spring it is apt to be taken up by the first two coils alone, which are thus placed under severe strain and may be ruptured. Still another advantage is that, in view of the slight thickness of the material, it can be more thoroughly tempered. Among the applications which suggest themselves for the new tubular spring, the first that occurs to one's mind is its use for the alighting members of an aeroplane, in which it will replace the usual rubber bands. So far as weight is concerned, there will be a slight advantage in favor of the tubular spring; as regards working efficiency and durability, the tubular spring is far ahead of the rubber band. The theory of the tubular spring follows along the same lines as that of the tubular rod. As is well known, it is the outer fibers of a rod which are placed under the greatest strain in bending, while the central fibers are practically unstrained. Thus the tube is obviously the most advantageous form for a member which is to sustain bending stresses, inasmuch as all the peripheral fibers, that do the main work, are present, while the central fibers, which are comparatively useless and merely add ballast, are simply eliminated.

Root Shield for Sewer Pipes.—In their search for moisture the roots of trees are very apt to work their way between the joints of sewer pipes, eventually obstructing the pipes to such an extent that they are completely clogged. Then it is necessary to tear up the ground and cut away the roots, for it is impossible to clear the pipes in any other way. This trouble is due, of course, to the fact that sewer pipes are ordinarily loosely telescoped, which results also in leakage at the joints. To protect the pipes against roots, an inventor has recently devised a guard, consisting of two telescoping shield members, adapted to fit over the joint. The flared end of one of the pipes serves as an abutment for one of the shield sections, while a lead ring serves a similar purpose for the other shield section. The space enclosed by these sections is filled with cement. The two shield members are coupled by means of cross pins, fitted through ears in one member and bearing against lugs in the other. The accompanying drawing shows a guard in section as well as an exterior view. It also shows the effects of the roots on an ordinary sewer pipe.



Sewer pipes protected and unprotected from roots.

Refrigerator for Show Cases.—With a view to displaying meats and other provisions in a show case, while keeping them fresh and in a wholesome condition, an inventor has devised a novel form of refrigerator. The accompanying sketch shows a sectional view of a portion of a show case equipped with this system. At the right hand end is the refrigerator proper, consisting of a box provided with a perforated tray or rack, on which a block of ice may be supported. A large port connects this icebox with a compartment below the showcase proper, and here a fan is provided, which serves to drive air through a tube leading to the opposite end of the show case. A constant circulation is had by providing a port to connect the show case with the upper part of the refrigerating box. The arrows show the course of the air. The inventor has found that by this means he may cool the meats in his show case sufficiently to cover them with a coating of frost even in warm weather.

Show case refrigerator.

Rest for Tobacco Pipes.—One of the disadvantages of the ordinary tobacco pipes is the fact that it cannot be laid down without danger of spilling the tobacco ashes, and there is even the possibility of accidentally setting fire to material coming in contact with glowing embers of tobacco. To prevent such conditions a Canadian inventor has designed a clip adapted to grasp the stem of the pipe and provided with legs which will support the bowl of the pipe in an upright position. These legs may be folded against the stem when desired. Instead of employing a clip, he also provides a ferrule or sleeve, equipped with supporting legs, which may be used to connect the stem with the mouth-piece.

Rest to hold a pipe bowl upright.

Combined Salt and Pepper Shaker.—An inventor has recently hit upon a scheme for combining salt and pepper shakers in such a way that one will act as a cover for the other so that each condiment will be kept in an inclosed receptacle, in which no moisture may normally enter. Each receptacle is complete in itself but is connected to the other by a pair of channel-shaped plates which engage flanges on the meeting edges as shown in the cross-sectional view, Fig. 2. Salt or pepper may be shaken out of this combined receptacle on sliding one member upon the other so as to uncover a set of perforations in the face of the compartment from which the desired condiment is to be taken. Figure 1 in our drawing illustrates the shakers moved to such position. After one has helped himself to a quantity of salt or pepper he cannot stand the shaker upon the table with the parts in the position illustrated, for they will not hold their equilibrium. In order that the shaker may stand upright, the two members must be slid back to normal position, so that each will rest on the table.

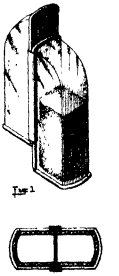


Fig. 1.

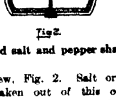

Fig. 2.

Combined salt and pepper shaker.

Machines for Dealing Cards.—Two machines for dealing cards are described in a recent issue of *La Nature*. One of these devices, which is extremely simple is represented in Figures 1, 2 and 3. The pack of cards is placed in a box *B* (Fig 1), which it fits exactly and which is open at one end. A rubber wheel *R* turning on an axis one end of which, *M*, is fluted so that it can easily be turned with the fingers, is brought to bear upon the cards by turning the hinged arm which carries it. When the wheel is turned in one direction, as shown in Figure 2 it expels the top card, when this object has been effected the motion of the wheel is stopped by the impact of the arm *D* upon the pack of cards. The wheel is then rotated in the opposite direction (Fig 3) until the arm *D* strikes the edge of the box. This reverse motion serves to replace any of the upper cards which may have been dislodged slightly in dealing the first card.

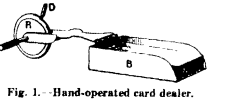

Fig. 1.—Hand-operated card dealer.

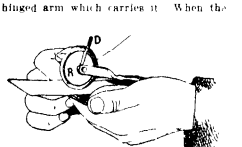

Fig. 2.—Dealing a card.

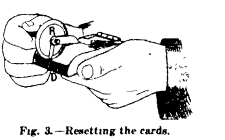

Fig. 3.—Resetting the cards.

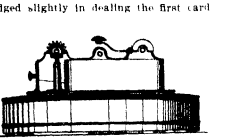

Fig. 4.—Power-operated card dealer.

The operations above described are repeated for each card. With a little practice cards can be dealt very quickly and thrown to a considerable distance. When the front of the pack is pointed slightly upward, the cards turn in the air before falling, but if the direction of

the pack is slightly downward the cards do not turn. Hence the cards can be dealt with their faces up or down, at will. The other machine, the invention of J. Olivier, is automatic and much more elaborate. It is designed especially for the games of bridge and whist, but it can be adapted to other games, using packs of 32 or 52 cards. The machine (Fig. 4) works silently and occupies little space. It is wound up with a key for a certain number of deals, 10 or 12, and a bell gives warning that the machines must be wound up after the next deal. A circular base, resting on rubber feet contains the clock work and supports a rotating platform on which the cards are placed. The platform is turned by a ratchet wheel, a quarter-revolution at a time, and at the end of each motion a rubber cam projects the top card in the direction of the player. The apparatus stops automatically after each deal. It is started by placing the cards in position and pressing a button.

Notes for Inventors

New Vacuum Cleaners.—A vacuum cleaner operated by gas is a new thing for which one great advantage is claimed and that is that it destroys the dirt which finds its way into its interior. Thus it is not necessary to empty the machine. It is not designed to be portable but to be built into the cellar of the house with pipe connections with each floor. It is only necessary to start the engine which is like any small gas engine and very simple to manipulate and then to make the necessary connection with the hose at the point of operation. The dust taken from the floor returns to the machine, where it passes through the flame and is entirely destroyed, the dust passing up the chimney with the exhaust of the engine. In the creation of the vacuum, superheated steam is used. Water is fed into a coil through a needle valve and as it drops from the point of entry, it is turned into steam and finally into superheated steam. The latter is then carried through a curved pipe and forced through a small nozzle into a cone shaped chamber. The action of the steam in rushing into the chamber forms the vacuum. The force of this is said to be sufficient to lift an ordinary building brick and hold it in mid-air. Another of the recent improvements in vacuum cleaners is one which is worked by the water power secured from an ordinary faucet. The device is designed either for portable use or stationary installation. The machine weighs but twenty-two pounds and may be readily carried around the house and placed wherever there is a convenient water outlet. A short tube connects it with the water pipe and a longer one of non-collapsible rubber permits the application of the vacuum at the desired point, remote from the machine. In the handle of the apparatus there is an observation glass for the purpose of watching the work. The machine is successfully operated by a pressure of fifteen pounds which is available in most all water systems. One of the newest features for the convenience of the automobilist is a small vacuum cleaner which is operated by the exhaust from the engine and this is useful not only in the cleaning of the interior of the car but also in removal of the accumulation of dust from the clothes of the passengers after a long ride.

A Pocket Camera.—It is always the big fish that get away and the big game that is encountered by the would-be sportsman when he is without his gun. So the camera worker realizes that he misses many desirable views and snapshots because these opportunities are met with at times when he is minus his camera. Even as compact as these instruments have been made by modern ingenuity it is not convenient to have one's camera always in hand. Hence many excellent views are lost, for it is generally impossible to return to the spot on another occasion and find the same combination of elements which goes to make up a desirable composition. The newest arrival in the camera field is a really and truly vest pocket one, and in such a shape as this the photographer may never be caught unawares. It is not a toy, but designed for serious work. It makes use of either plates or cut films measuring one and three-quarter inches by two and a quarter. These are carried in holders. The instrument is fitted with a fine lens and the pictures made are of such a character that they will stand enlargement up to six and a half inches by eight and a half under all ordinary circumstances; but if the original negative is made under favorable conditions, the enlargement may be greater. While direct prints make very pretty pictures, it is designed that generally enlargements shall be made. For this reason an enlarging machine has been designed for the special purpose of making prints from these negatives. It is so complete that enlargements may be made quite as readily as direct prints. The camera is made in two parts, one carrying the lens and the other the plate. These two are held together by the bellows and a spring hinge. When the parts are collapsed the whole forms a small and compact package which readily slips into the pocket. In fact, the whole outfit complete takes up but little room in the traveling bag or in an emergency could be carried in two pockets.

Young Stokes Takes Out a Patent.—William E. D. Stokes, Jr., of New York city and George W. Davis of Galilee, N. J., assignors to W. E. D. Stokes of New York, have secured a patent, No. 1,001,227, for an aerial for wireless telegraphy and telephony and 1,001,228, for a receiving circuit in the same art. The aerial patent provides two vertical points of support with a wire between them and a series of vertically arranged wires standing in a plane and a switching device by which any of the aerial wires alone can be connected to the receiving circuit. The receiving circuit includes a large copper plate connected to the aerial and embedded in insulating material and supported parallel with the ground by insulating standards.

A Barbed-wire Improvement.—In the manufacture of barb-wire, which is turned out in great quantities, it has been heretofore necessary to make use of a double strand of wire, the two being twisted and the sole use of the extra strand is for the purpose of holding the barb in place. A new machine for the manufacture of this article has been recently perfected by which the barb is pressed in place firmly around a single wire. This saves wire in two directions, namely, in the use of the extra strand and in the cutting of the barbs, the latter being twisted only once, while formerly they were given a double twist. The new machine also has the advantage of increased speed and economy of operation.

Stopping Trains When the Motorman is Killed. Trains of the Interborough lines and those of the Hudson tunnel are being equipped with a safety device which overcomes the possibility of a train running wild when the engineer is killed, injured or otherwise incapacitated. It consists of an electric button which is placed in the handle of the controller and normally, when the operator is at his post, this is in a depressed position, but the instant his hold on the handle is released for any cause whatever an electric circuit is made and the brakes of the train are set.

Erratum

IN our issue of September 16th we published an article entitled "Inventing for the Public." Among the portraits of the government officials who had given their inventions to the public, appeared those of L. W. Page, director of the office of Good Roads, and J. E. W. Tracy. Through an error Mr. Page's name appeared below Mr. Tracy's portrait, and Mr. Tracy's name appeared below Mr. Page's.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

GARMENT FORM.—E. T. PALMENBERG, New York, N. Y., and F. W. KASSUBA, Bayonne, N. J. In this form the arm pieces can be readily removed for fitting purposes, at the same time showing a correct armhole outline. The arm pieces are provided with armhole patterns, of which one has a tongue for engagement with a keeper on the other pattern, to removably connect the arm piece with the shoulder.

SHOE SHINE PROTECTOR.—R. B. LUTHER, Pipestone, Minn. The purpose here is to provide a novel one-piece self-closing protector which will cover the hose adjacent to the shoes while the latter are being cleaned, polished or shined, thus preventing the soiling of the hose. The protector may be used for both low and high shoes.

Of General Interest.

LIFE PRESERVER.—J. STROZEL, New York, N. Y. The main feature of this invention involves the automatic closing of a normally open air inlet valve by the securing of the life belt in position upon the person. The belt is mechanically distended when being strapped on, and this distension draws air into the air chamber, and then automatically closes the air valve, to prevent the escape of the air or the entrance of water.

METAL FRAME FOR GLASS PANES.—A. RUSSE, New York, N. Y. The object of the present invention is to so join the bars that no unfilled openings or protuberances will be presented at the points of intersection in the finished frame, producing an interlocked frame structure of relatively high strength. The invention is an improved metal frame for glass of the character disclosed in Letters Patent No. 942,811 formerly granted to Mr. Russe.

PROCESS OF REFINING AND DESILVERING LEAD.—C. P. HUEY, Omaha, Neb. This improvement relates to refining and desilvering by the crystallization process. The aim is to provide a method for refining and desilverizing lead bullion and impure lead, and whereby the number of crystallizing operations is reduced to a minimum for the proper production of high grade bullion or metal running five hundred to six hundred ounces silver and a market lead.

CAR LOCK.—F. D. STARIN, Whitewater, Wis. The object of this inventor is to provide a device to permit of car lock adjustment to counteract the effects produced by wear. Another object is to provide a device of simple and serviceable construction, inexpensive to manufacture, which is adjustable so as to render the car locks practically noiseless while in operation and also to overcome lost motion occasioned through wear.

NON-REFILLABLE BOTTLE.—S. O. STAUCH, Anaconda, Mont. In this case if any attempt is made to force a liquid down into the bottle the pressure will cause the thin glass strip which holds a valve and ball to break thereby permitting the valve to seat against a valve seat while the ball will roll to the bottom of a conduit, breaking a thin glass partition and will seat itself on another valve seat, which prevents any liquid from the outside from entering the bottle.

ATTACHMENT FOR SUIT CASES AND THE LIKE.—L. SPRY, Clarksburg, W. Va. An object here is to provide a device by means of which that portion of the suit case upon which the lock is situated may be effectually braced, so that when the lock is sprung together it may have a resisting part which prevents the bending of the side of the case and, hence, the failure of the lock to work.

CUTTER FOR WELL CASINGS.—H. MEAD, Coalinga, Cal. Mr. Mead's invention is a cutter for use in removing the casings of oil wells and the like when for any reason the whole string of tubing constituting the casing cannot be pulled. It comprises a supporting head in which is mounted a series of cutter wheels and cutter knives, the number of wheels being equal to the number of the knives in each case, and all the knives and disks being located in the same transverse plane.

SHIP OR VESSEL.—G. E. ELIA, Hotel de Crillon, Place de la Concorde, Paris, France. This invention relates to ships or vessels and is particularly applicable for use in connection with vessels employed in naval warfare, the object being to preserve the stability of the same in the event of their being subjected to the effects of a submarine explosion. This application is a divisional application of one filed formerly by Mr. Elia, the serial number of which is 568,304.

Heating and Lighting.

GAS GENERATOR.—C. F. RUKES, Kansas City, Mo. The hopper in this generator is filled with carbid, and the casing is supplied with water. Whenever the gas in the casing does not exert sufficient pressure to push the diaphragm outwardly, the free end of the switch lever falls between contact [illegible] closes the circuit, thus energizing [illegible] ners. Means provide for shaking the carbid into the water, which generates and opens the circuit. Means are provided for preventing any great amount of carbid from leaving the hopper. The operation is entirely automatic and [illegible] cally constant pressure of gas is maintained.

Household Utilities.

COMBINATION COVER AND DRAINER.—H. GIBSON, Ridgewood, [illegible]. The object in this instance is to provide a new and improved combination cover and drainer, more especially designed for the wash tubs located along the sink or a similar receptacle, the device being arranged to permit its use as a cover for the wash tub or as a drainer for the dishes.

CLOTH FOLDER FOR IRONING.—H. [illegible] RAND and M. M. GRAY, Creecy, Iowa. This device is for use in folding the edges of cloth, strips, or ribbons when being ironed or pressed. The device will operate to fold the edges of the cloth, and also to form a seam for the edge of the iron, enabling the device to be guided in its movement along the strip, cloth, or ribbon.

CLOTHES LINE CLAMP.—W. C. LEA, Chickasha, Okla. The object here is to provide a device which may be easily placed and removed, and which may be locked on the line with or without clothes thereon, and which may be easily and cheaply constructed. When not in use the clamp may be clamped on the line or may be removed if desired. When clamped on the line, the clamp is retained firmly in position and cannot become loose.

Machines and Mechanical Devices.

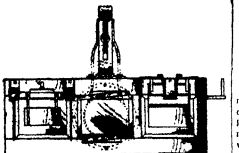
DISSOLVING VIEW APPARATUS.—H. KRIEGER, New York, N. Y. This invention has reference to optics, and its aim is to provide a dissolving view apparatus, arranged with a single source of light and one lamp casing, thus simplifying the construction of the apparatus and requiring less adjustment and attention on the part of the operator.

DRILLING DEVICE.—R. R. SANDERSON, Orrville, Ohio. An object of this inventor is to provide a device of the walking beam type in which the rapidity of the operations of the drill rod may be considerably increased without sacrificing its effectiveness in any particular, thereby rendering the machine capable of doing more work in a given time than the ordinary drilling device.

ROCK DRILL MAKING AND SHARPENING MACHINE.—M. MCHALE, Phœnix, British Columbia, Canada. This invention provides means for shaping through successive operations the heads of drills as desired to provide means for varying the dies for forming the said heads; provides a sharpening and setting mechanism which may be rapidly and easily varied as to size and design; provides a battery of guiding means to operate in conjunction and unison with the sharpening and setting devices carried by the sharpening mechanism, and provides a machine with an adjustable anvil having a plurality of pockets to hold drills of varying lengths.

VENDING MACHINE.—C. J. FROHL, San Jose, Cal. This machine is for use in dispensing small west account books or the like, which upon the insertion of a specified coin will deliver a single book, and wherein an efficient means is provided for preventing its operation without the insertion of the proper coin, and wherein the coin is utilized to restrain the operation of the machine.

FOLDER FOR SEWING MACHINES.—C. E. MCLIN and J. S. BACHMAN, Rome, Ga. The machine provides a folder suitable for folding cloth in making back bands. The invention comprehends an improved type of mandrel made in two massive parts detachably connected together and so formed that when a piece of suitable material is guided through this mandrel, the material is folded properly to be sewn by the machine and thus made into a back band.



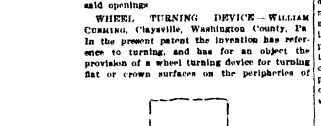
FRICTION CLUTCH.—F. D. ODDEN, Boston, Mass. An object of this invention is to provide a device extremely sensitive in its operation and unaffected by oil, also to provide a plurality of members adapted to be driven one from the other, one of said members having a plurality of spring contact members adapted to be forced into engagement with a clutch face on the other member.

DUST PROOF STEM AND SLEEVE.—D. W. SHEPHERD, Pocatello, Idaho. This improvement refers to open face watches, and its purpose is the provision of a new means for rendering the watch case dust-proof at the stem, to allow convenient adjustment of the stem for winding and setting purposes, and without danger of end shake or breaking.

PROPORTIONING WEIGHING MACHINE.—R. M. CAMPBELL and J. R. TAYLOR, Terrell, Texas. This invention provides a plurality of measuring mechanisms arranged to automatically suspend the delivery of material therefrom; provides an electrically-operated means for dumping one or more of said mechanisms simultaneously; and provides means whereby the number and combination of the weighing apparatuses may be regulated and controlled.

WRITER ATTACHMENT.—J. B. New York, N. Y. This invention re- an attachment whereby the operator in operating the typewriter by the system." A further object is to pro- frame which will divide the various groups into alales by means of suitable and which will further sub-divide the same into tiers by means of stops, whereby the operator's hands are automatic- returned to their position relative to the keys on the typewriter.

MAGIC LANTERN.—ARTURO PAOLI, South Bend, Mich. This invention is an improve- in magic lanterns and a front view of it is shown in the accompanying engraving. The object of the invention is to provide a simple and easily operated mechanism for shifting the picture slides in devices of the character specified, and in such manner that



MAGIC LANTERN.

the pictures will merge into one another without any abrupt demarcation between them. As shown in the illustration, the device extends upon both sides of the projector, so that there is space for a slide in front of the projector and space for a slide on each side of the projector. A magazine is provided for use in receiving the used slides and for temporarily storing them.

AIRSHIP.—T. M. CREPAR, Dilworth, Minn. Mr. Crepar's invention pertains to airships, and its object is to provide one with a plane the sides of which converge rapidly at its forward end, said sides converging slowly toward the rear, thereby forming an elongated tail, making the plane substantially fish shape. Another of the objects is to provide two planes, one disposed above the other, there being several openings in each of the planes, and a series of vanes being disposed in each of the said openings.

WHEEL TURNING DEVICE.—WILLIAM CUMMING, Clayville, Washington County, Pa. In the present patent the invention has reference to turning, and has for an object the provision of a wheel turning device for turning flat or crown surfaces on the peripheries of

WHEEL TURNING DEVICE.

wheels too large to be mounted on a lathe. For the purpose mentioned use is made of a bed provided with a straight track and a curved track, a tool carriage mounted to operate on the tracks, and means for operating the carriage over either of the tracks. The illustration gives a plan view with parts broken away to disclose the carriages operating over the curved track.

MOTOR CONTROL APPARATUS.—D. WALD, O. C. BRITSCH and M. TAUBMAN, New York, N. Y. This apparatus may be used in connection with any suitable mechanism, but is especially adapted to be applied to a power sewing machine. The motor control will simultaneously throw the switch with the movement of the control arm, so as to prevent the sparking on the resistance contacts, thus increasing the life of the latter.

SWEEPING MACHINE.—L. B. HOOKER, San Francisco, Cal. The aim in this case is to provide a machine having means by which the rotary brush may be adjusted to any one of a plurality of positions relatively to the frame, with means by which the driving mechanism, supported by the frame, may be quickly adjusted for operating the rotary brush after it has been adjusted.

ELEVATOR.—F. SCHWARM, Berne, Ind. The elevator has a counter weight, the cage or elevator platform being provided with a windlass adapted to wind a heavy balance chain secured to the counter weight so that the excess weight of the chain may be shifted from the cage or elevator to the counter weight and back again as may be desired.

STEAM TRAP.—G. KIESLING, Scranton, Pa. This improvement comprehends particularly a trap having a shifting weight of improved construction arranged in connection with a reservoir for the purpose of facilitating the step of raising the reservoir and of preventing its re- from to normal position until all of the water of condensation is discharged, the return of the reservoir then being effected by the reaction of the weight, under control of gravity, to its normal position.

INSTRUMENT FOR USE IN NAVIGATION.—OTH B. SANDERS, Key West, Fla. This invention relates to a new and improved instru-

INSTRUMENT FOR USE IN NAVIGATION

ment for use in navigation, whereby the true course is determined from the compass course in the shortest possible space of time, by mechanically allowing for the deviation and variation. An object of the inventor is to pro-

VERTICAL SECTION OF INSTRUMENT.

vide an instrument with a plurality of relatively adjustable circular graduations whereby the various deviations and variations may be allowed for. The invention is fully illustrated in the accompanying engravings. The large one is a top plan view and the other a vertical section of the line 2—2. It is inexpensive to manufacture, readily accessible, and easily operated.

CHECK CONTROLLED STAMPING MACHINE.—P. LAMBERTI, New York, N. Y. This device on the insertion of the proper amount of change will impress on an article of mail matter a serial number, the hour and date of mailing, the station or box mailed at, and an inscription stating that the required amount of postage has been paid, whereby a great saving in the handling of letters, and the number of clerks necessary to sell stamps, will be accomplished, and further, whereby any pilfering of the postage money or of letters themselves will be immediately detected.

Prime Movers and Their Accessories.

PACKING FOR PISTON RODS.—J. A. BOLCH, New York, N. Y. Among the principal objects in view here are to provide a packing for piston rods universally connectible to preserve the parallel relation of the bearing surface to the piston rod, and to provide an elongated packing for piston rods constructed from metal and arranged to contract evenly throughout its length upon the rod.

GAS TURBINE.—F. KRAUSE, Babylon, N. Y. This invention relates to certain improvements in turbines and more particularly to that type of turbine in which an explosive mixture is ignited in a separate chamber and admitted to the blades of the turbine. One of the important features is the means employed for controlling the explosive mixture and the delivernce of the same to the blades of the turbine.

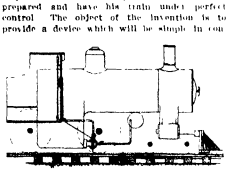
INTERNAL COMBUSTION GAS-TURBINE ENGINE.—E. ANWELL, Baltimore, Md. This invention provides an engine wherein the explosive mixture is primarily compressed and exploded while so provides an explosion chamber wherein is exploded the compressed charge of explosive mixture while establishing communication between the said chamber and the turbine rotor, provides a reciprocating mechanism for compressing and firing the mixture as distinguished from the turbine mechanism and provides an engine employing in mutual operative relation a reciprocating explosion chamber and a turbine shaft driving rotor.

EXPLOSIVE ENGINE.—W. W. WELLS, Clyde, Ohio. In the present patent the invention is an improvement in multiple-cylinder engines, particularly engines in which the cylinders are arranged in pairs and are co-operative with each other in the introduction of scavenging air preparatory to the admission of the explosive charge.

INTERNAL COMBUSTION ENGINE.—A. M. CLEMENT, New York, N. Y. This invention provides sliding-valves arranged and constructed to avoid leakage of gas due to wear of the sliding parts; provides a simplified construction for valves whereby expansion pressure is relieved therefrom during movement thereof; and provides a valve operating mechanism embodying a single cam and simplified transmission mechanism connected therewith.

ROTARY ENGINE.—HENRY HEYER, New York, N. Y. This invention relates more particularly to an engine comprising a stator casing, a rotor in the casing, a steam chest, a movable steam duct therein adapted to be arranged in different positions to direct the fluid under pressure into the casing in different directions, and vanes carried by the rotor and adapted to receive the fluid at opposite sides according to the position of the steam duct.

TRACTION ENGINE.—D. O. DEWITT, Aberdeen, S. D. The objects here are to provide a traction engine which may be operated with a minimum of power, especially over soft ground; to simplify the construction by cutting parts usually employed in the running gear, to provide facilities for steering and piloting the machine over uneven and soft grounds with freedom, by a single operator, and to dispense with the differential gear used in machines of the class to which the invention belongs.



Railways and Their Accessories.

TRACK MOVING MACHINE.—E. L. HAYWARD, Davenport, Iowa. In this patent the invention has reference to improvements in means or apparatus employed in handling steel and ties in track construction. The intention here is to provide means or apparatus for use especially in timber lands, whereby the handling and transportation of track material is facilitated.

METALLIC TIE AND RAIL FASTENING DEVICE.—J. F. ROBINSON, Atlanta, Ga. An object of this inventor is to provide a tie which shall form a resilient bearing surface, thereby absorbing shocks. The tie will prevent the spreading of the rails and the accidents consequent thereto. A spring rail fastening device is provided which holds the rail in fixed position, thereby doing away with the usual method of fastening rails by spikes.

RAILROAD CROSSING.—J. B. DUNLAP, Tulsa, Okla. An object in this instance is to provide a crossing which obviates the usual jars incident to the passage of a train over the crossing. This is accomplished by providing movable track sections which may be so moved as to complete the track in either direction so that the tread of the wheels may move on a continuous bearing surface.

OPEN SWITCH SIGNAL.—THOMAS J. RICE, Office Quartermaster's Dept., U. S. Army, Honolulu, Hawaii. This invention has reference to a means of warning an engineer that he is approaching an open switch rather a quarter of a mile off, so that he may be prepared and have his train under perfect control. The object of the invention is to provide a device which will be simple in con-

OPEN SWITCH SIGNAL.

struction positive in its action, and which will have the fewer parts consistent with accurate working and which at the same time will be strong and durable. The engraving shows the signal attached to the engine and a tripping mechanism located on the track. Means provide for making the signal sounding mechanism inoperative when desired.

CAR WHEEL FLANGE LUBRICATOR.—J. L. FERRIS, Montezuma, Mexico. The invention relates to an automatic car wheel lubricator, and provides a device which will positively supply a lubricant to the flanges of the car wheels when they are rounding curves to prevent friction between the car wheel flanges and the rails, the lubricant being fed in atantaneously and in sufficient quantities

Pertaining to Recreation.

MOTOR CYCLE TANDEM ATTACHMENT.—W. P. SPENCER, San Jose, Cal. The object of the invention is to provide an attachment by means of which the ordinary single passenger motor cycle may be converted into a two passenger vehicle with the seats tandem without any changes in the structure of the vehicle itself. The attachment is simple and inexpensive and easily attached and detached. No change is necessary in the construction of the cycle.

TROLLING HOOK.—J. P. THOMSON, Owen Sound, Ontario, Canada. The invention relates generally to trolling hooks for fishing, and the principal purpose is to provide a hook having the spoon or bait revolubly mounted thereon so that when in the water the spoon or bait will be attractive to the fish, the spoon being revolved as the hook is drawn through the water.

TOY.—M. A. BURRIS, University, Va. In this invention the improvement is in toys, and its object is the provision of a simple, cheaply constructed toy, especially designed to afford amusement, while at the same time developing quickness of observation, and dexterity of hand. A nut catches the game piece when the operator fails to properly place the piece and an opening permits the said piece to be returned readily to the shank.

Pertaining to Vehicles.

WAGON BOX FASTENER.—H. F. BART, Broken Arrow, Okla. The purpose of this improvement is to provide a simple inexpensive and easily operated device for use in holding the parts of the box together without injuring the same, which may be quickly applied or removed. The device consists essentially of a pair of telescoping members or bars each having a clamping jaw at the outer end co-operating with the jaw of the other member and a clamp for holding the members in adjusted position.

AUTOMOBILE AIR PUMP.—C. CLEMENS, New York, N. Y. The invention provides a pumping mechanism operatively attached to the driving axle of an automobile for inflating the tires of the wheels not directly connected with the pumping mechanism; provides means for manually operating the pumping mechanism independent of the wheel and power driving mechanism of the automobile, provides means for uniting the wheel of the automobile with which the pumping mechanism is connected as a fly wheel for the pump when the same is manually operated, and provides means for rigging a drum on an automobile driving wheel to extend about the axle when carried thereby to inflate the tire of the wheel on which it is mounted.

SIGN HOLDING DEVICE.—W. A. RINGS, 1022 Ionia Street, Grand Rapids, Mich. In this instance the invention pertains to devices for holding signs more particularly those that are to be used to display the license number of automobiles. An object is to provide a device by means of which a sign may be held rigidly in position so that there will be no danger of the sign's becoming loose and dropping from the vehicle.

WIND SHIELD.—J. H. SCHAUER, Norwalk, Ohio. This invention refers to shields adapted for use upon motor vehicles, and more particularly to that type of shield which has a transparent section movable to operative or inoperative position. One important feature includes the use of rollers within the hinge and fitting in V shaped grooves for locking the sections of the shield in predetermined relationship.

TAXIMETER CONTROL.—J. D. SULLIVAN, New York, N. Y. In this case the invention refers to a new and improved attachment for taximeters whereby the taximeter may be controlled so that the chauffeur cannot conventiently operate the taximeter without recording the distance traveled when the taximeter is occupied by a passenger.

SPRING WHEEL.—O. H. HINDS, Le Mars, Iowa. This invention provides a novel construction of spring wheel in which the lateral rigidity incident to or characteristic of the ordinary automobile wheel will not be impaired and in which springs may be utilized to secure the desired resiliency of the wheel in a radial direction in a simple and efficient manner.

TIRE.—O. H. HINDS, Le Mars, Iowa. In this patent the invention is an improvement in tires and particularly in the means for excluding dust, dirt and the like from the joint between the flanges from the rim and the tire which is movable radially in said flanges, the present application being a division of an application formerly filed by Mr. Hinds.

SPOKE FOR WIRE WHEELS FOR VEHICLES.—W. P. PECK, Jr., Buffalo, N. Y. The rim of this wheel is divided transversely so that it is formed practically in halves or nearly equal semicular sections one of which is fast on the steering shaft and thus constitutes a hinge and thus adapted to be raised and folded back upon the fixed section so that it will not obstruct the chauffeur in entering and leaving his seat.

VEHICLE WHEEL.—A. BROOKES, Lancaster, Wis. The invention relates to improvements in automobile wheels and particularly to the tire thereof, whereby an increased durable resiliency is obtained. An object is to provide a tire composed of a plurality of resilient members, preferably of a metallic nature, spaced apart and connected together to form a continuous resilient element.

Designs.

DESIGN FOR A GLASS GOBLET OR SIMILAR ARTICLE.—C. O. NORTHWOOD, White Mills, Pa. In this ornamental design of a glass goblet, the article is of the elongated type of bowl and stem, the whole set in a somewhat flat stand. The flowers, leaves and tendrils decorating the glass are of peculiar interest and beauty. Mr. Northwood has another design which is very much broader and shorter than the one described and set upon a very short stem the ornamental feature being at the rim and extending about one-third down the length of the bowl-shaped body.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention and date of this paper.

NEW BOOKS, ETC.

THE AEROPLANE By Claude Grahame White and Harry Harper Philadelphia J B Lippincott Company, 1911 317 pp 93 illustrations Price, $3.50

Although the title of this book reads "The Aeroplane Past Present and Future, by Claude Grahame White and Harry Harper, only a few articles are to be credited to Mr Grahame-White or to Mr Harper and why they should figure as authors seems somewhat mysterious As a popular book on aeroplanes, the book is likely to serve a useful purpose, even though there are probably now no less than three or four dozen simply worded volumes on aeroplanes struggling for existence in the book market Much practical information is not conveyed By far the best article in the book is that by H Chippere discussion of the aeroplane in warfare, a sane presentation of the possibilities and limitations of the flying machine for military purposes For popular reading, the book can be commended, but for valuable technical information, the reader will find it far too ephemeral

DIE EXPERIMENTIELLE GRUNDLEGUNG DER ATOMISTIK Von Werner Mecklenburg Jena Gustav Fischer, 1910 140 pp Price, 250 marks

The atomic hypothesis has long possessed a double sphere of usefulness To the chemist it has represented a most convenient picture by means of which to express in simple terms the laws of chemical combination So convenient, indeed, to the chemist has been the language of the atomic theory, and so generally adopted has its use become that when Wald pointed out, some years ago, how all the facts of stoichiometry could be accounted for without recourse to this hypothesis, he found himself speaking to a rather unappreciative audience Wald probably would have passed almost unnoticed but for the authoritative support lent to him by Ostwald in his Lansday lecture and on other occasions There seems to be little doubt that the evidence of chemistry alone would have been insufficient to firmly establish the atomic hypothesis But, on the other hand, this hypothesis has been of supreme interest to the physicist firstly in its relation to the mechanical theory of heat with its off shoot, the kinetic theory of gases, of solutions, and latterly also of suspensions, and secondly, in the development of the electron theory The evidence which has thus accumulated in favor of the atomic hypothesis is now well nigh irresistibly convincing so that even Ostwald, formerly so strongly opposed to the atomic point of view, openly declares himself its adherent, and definitely accepts the atomic constitution of matter as one of the basic starting points of chemical science, in his last edition of his "Outlines of General Chemistry The author of the book under review may be envied for the extremely graceful task which he has undertaken that of laying before the reader a concise and yet essentially complete account of a field of physical science, which has from the first possessed features of remarkable interest, but which especially in late years has brought forth developments having short of spectacular Have we not to day direct optical evidence of particles very little greater in size than the calculated diameters of an ultimate molecule? Have we not, it be said, display all the characteristic properties and phenomena foreseen by the theoretical physicist in his investigations of the nature and behavior of molecules If the determination on theoretical grounds of the molecular dimensions by the work of Clausius, Maxwell, Boltzmann, impresses us as a triumphal feat of human intellect the confirmation of their conclusions by direct experiment comes as a crowning testimony, both to the power of that intellect and to the resources of experimental skill And if the subject is one of remarkable interest, the author has been equally fortunate in his treatment of it In the course of four chapters he has led the reader in simple terms the main experimental facts and theoretic ideas of reasoning upon which the modern structure of the atomic hypothesis is built The first chapter is headed "The Existence of Discrete Particles in Seemingly Homogeneous Solutions" the second deals with

The Dimensions of the Molecules as Determined by the Kinetic Theory of Gases" The third chapter is devoted to that remarkable phenomenon known for some time but almost forgotten by the physicist the Brownian movement which has quite recently proved such a rich mine of information of the highest importance in the final establishment of the atomic theory upon an experimental basis The fourth and last chapter deals with another subject the study of which has proved one of the most fertile fields of modern physical research, and has contributed immensely to the very cornerstone of the atomistic point of view

The author has succeeded in striking a most happy medium between a purely popular presentation on the one hand which for lack of detail would fail to give the reader a true insight into the nature of the very remarkable developments discussed and on the other hand, a highly technical treatise from which only the specialist could derive any advantage The book is most highly recommended to all who take an interest in the chemical and physical phenomena to which it refers, and quite especially to those who, having at least some knowledge of the subject, wish to refresh their memories on familiar points, and to bring their acquaintance with a most fascinating province of physics up to date It is heartily to be wished that translations of this work into English and French may soon appear upon the book market

A few such errors as unavoidably occur in a first edition have been noted in perusing the book and may be listed here for the benefit of the reader On page 22, line six from below, the symbol x has apparently been omitted after the word "Höhe" This might possibly cause some confusion On page 23 it is stated that a table of molecular dimensions, etc., is appended at the end of the book In point of fact, this table appears between pages 64 and 65 On page 106, the word "Gramolekülen" should evidently be Grammolekülen" These trifling errors do not of course, in any way detract from the very high value of the book before us

POWER By Charles E Lucke, Ph D New York The Columbia University Press, 1911 316 pp Price, $2 net

In 1910 Prof Lucke delivered a series of eight lectures on the phases of power These lectures have now been incorporated in book form in a worthy manner The titles of the lectures are the following I The Relation of Mechanical Power and Machinery to Social Conditions, II Means Employed for the Substitution of Power for the Labor of Men, III Essential Elements of Steam Power Systems, IV Principles of Efficiency in Steam Power Systems, V Processes and Mechanism of the Gas Power System VI Adaptation of Fuels for the Power of Internal Combustion Engines VII Water Power Systems and Rental Hydraulic Processes, VIII Social and Economic Consequences of the Substitution of Power for Human Energy Such a subject could be well written with such clearness that a layman of intelligence ought to be able to understand them

A POTTERY PRIMER By W P Jervis New York The O'Gorman Publishing Company 1911 8vo, 188 pp., Illustrated Price, $1

It is not surprising that the art and craft of pottery should appeal strongly to the artistic heart of mind or that its products should have raised up an enthusiastic army of collectors Its history appeals to us on many sides It has associations which bind past and present, foreign and native It builds up common clue into expressions—often very beautiful expressions—of the higher mind It is flower-like in its fragility, in its blending of body and spirit Its symbolism has permeated the literature of the world for countless ages The Potter Primer" is the work for the individual preserment of body and mind—the technology processes and technique of the craft, together with not a little of the grace and ethereal freshness that belong to the art The Illustrations place before us examples of ancient treasures and more modern works and admirably serve the writer's avowed purpose to awaken the reader to a desire for further research In addition to the plates cups and vases which typify succeeding phases of history, we have glimpses of panels lantern, fountains and mantels of distinction This is really a more than usually good book and is a noteworthy addition to Mr Jervies earlier works on ceramics pottery and pottery marks

RADIUMNORMAL MASSE UND DEREN VERWENDUNG BEI RADIOAKTIVEN MESSUNGEN By E Rutherford Leipzig Akademische Verlagsgesellschaft m. b. H. 1911

In the course of the last decade our knowledge of radioactivity has rapidly widened Not only have the types of radioactive substances which emit radiations been carefully studied but much labor has been spent in trying to fathom the nature of the complicated processes which occur in radioactive matter A theory has been proposed which for the time being explains satisfactorily a great number of phenomena That theory, which is called the transformation or disintegration theory was first proposed by Rutherford and Soddy in 1903 and was based upon the supposition that the radioactive atom is unstable and that it decomposes with explosive violence at the same time emitting characteristic radiations As the result of this atomistic explosion a new atom is produced, quite different from the parent in chemical and physical properties These new atoms are also unstable, and give rise to another set of atoms Thus the process may continue for some time In the investigations of this kind standards of some kind are necessary This book of Prof Rutherford's which is no doubt familiar to many English readers in its original English expresses the necessity for a normal mass of radium and its use in radioactive measurements a matter which was discussed at the last radiological congress held in September, 1910, in Brussels

A YEAR IN A COAL-MINE By Joseph Husband Boston Houghton Mifflin Company, 1911 12mo., 171 pp Price, $1 10 net

Ten days after leaving college a young Harvard man became a laborer in a non-union coal mine of the Middle West—starting very literally at the bottom with the aim of learning the business thoroughly. The ordinary work and life of the underground city would alone make good reading at the hands of an educated man with a sympathetic knowledge of nature values but Husband was fortunate enough, or it is our good fortune, if you so prefer, in experience in that one short year all the thrills that strikes, fires, and explosions are capable of furnishing The result is a document of some value as a study of mining conditions, and of popular interest in so far as hazardous moments and adventurous days can make it

UNSOUNDNESS OF MIND. By T. S Clouston M D, LL.D, F R S E. New York E P Dutton & Co, 1911 8vo.; 360 pp., 14 illustrations. Price, $2.50 net.

Popular interest has of late years been quickened toward this important subject Criminals are more and more availing themselves of the plea of insanity in an attempt to escape punishment We still ridicule the weak-minded and subject the inmates of our insane asylums to unnecessary cruelties; but we are slowly learning that a diseased brain is as much a physiological fact as a diseased liver, and that no odium should attach to its victim Dr Clouston handles a most difficult subject in a manner nothing short of masterly The volume answers, or at least discusses illuminatingly, the most absorbing questions Since a man now appears to act irrationally, and an insane subject frequently presents no irrational thoughts or actions to our view, how may we distinguish between a sound and an unsound mind? If, in infancy, we look for the signs of the corresponding nerve cells of the motor centers in the brain shrivel up To what extent have we localized in the brain these various functionings? What proportion of guilt is usually found in crime? Are we all a little affected, as the well-known remark of the old Quakeress would lead us to mistrust or is our universal mind built upon a true foundation? Dr Clouston shows for us eleven orders of brain in their characteristic workings His conclusions are optimistic as his opposing facts well weighed The relation of heredity, of nerve exhaustion, of other causes, to unsoundness of mind and insanity, is made wonderfully clear and, not stopping at a mere presentment of the evil, suggestions *for preventive and curative regimen* are given The hopeless cases are differentiated from the hopeful, ranks from melancholy, the functional difficulties from the organic, and the workings of the brain are bared to the gaze in a way that all can understand The volume embodies the latest theories and discoveries, and clearly conveys knowledge that no parent at least should be without Its suggestions, if followed, would vastly decrease the world's troubles and result in the improvement of the human race

ELEMENTARY CHEMISTRY FOR COAL-MINING STUDENTS By I. T O'Shea New York Longmans, Green & Co., 1911. 8vo., 319 pp; illustrated Price, $1 50 net

As the name indicates this book sets forth such simple chemical principles as bear upon the work the welfare and the safety of coal miners and the value of their product The chapter on the air of coal mines can be adequately dealt with only by a fuller knowledge of chemical action and combination This touches the problem on its life-saving and property conserving sides On the purely economical side of the question, coal itself must be regarded as a combination of carbon, hydrogen, nitrogen, oxygen etc., and the proportions of these determine its value for particular purposes Its constituent parts are also taking a part of growing importance, in that it determines the value of a coal in its application to special uses Colliery explosions are made the subject of careful study The book should be cordially received by all who are interested in what it has to offer

ABROAD WITH THE FLETCHERS. By Jane Felton Sampson Boston I. C Page & Company, 1911 8vo., 368 pp.; Illustrated Price, $1 60 net.

"Abroad" has reference to the stereotyped circuit from Naples to Rome, Florence, Venice and Milan; through Switzerland and Western Germany with a dash up into the Netherlands and a descent through Belgium to Paris, thence to London, to Scotland, and back to Liverpool to take the homeward steamer "The Fletchers" are a quaint old couple of the usual type, through whose eyes all the old familiar sights are seen from a new angle The savings of Thomas Jeremiah Fletcher form no small part of the recital, which, showing a 'prentice hand, still atones by a certain freshness and spontaneity for any technical shortcomings The illustrations are from photographs by the author, and are very clear and good

HALF HOURS WITH THE SUMMER STARS. By Mary Proctor. Chicago: A. C. McClurg & Co., 1911. 232 pp.; Illustrated

In this little book Miss Proctor has given just the kind of information which the average astronomically uninformed man desires about the stars Not only does she give the mythological significance of the more important constellations of stars, but the result of most modern scientific discovery.

Kindly keep your queries on separate sheets of paper when corresponding about more than one subject. Please write your queries on one side of the paper only. Be sure to give your full name and address. Unless otherwise requested, queries will be published in the order in which they are received. Queries which require extended research cannot be answered in this department. Unless a self-addressed envelope is inclosed with the query, answers will be sent to correspondents by mail. Queries which are of general interest will be answered in the columns of this department. Unless otherwise requested, queries will be published in the order in which they are received. Queries which require extended research cannot be answered in this department. Unless a self-addressed envelope is inclosed with the query, answers will be sent to correspondents by mail. Queries which are of general interest will be answered in the columns of this department.

(12538) T E. W. says: Can you give me information in regard to silvering a speculum for a reflecting telescope. What formula and how to handle it? What chemicals shall I use in making high and low tension eyepieces for a 12-inch reflector of 72-inch focus? A. You will find in the SUPPLEMENT, No. 1071 the process for silvering a speculum clearly and fully described. In SUPPLEMENT, No. 1500 is a full and valuable article giving the data for eyepieces of a good range of focal lengths. We will send these for ten cents each

(12539) B. F. J. asks: Can you give me any information regarding paper that can be discolored by an electric current? A There are a number of ways of preparing paper so that an electric current will discolor it. The methods of rapid telegraphy are based on such an action The simplest is to use a paper which has been wet with a solution of starch and potassium iodide in hot water The paper turns dark at the positive pole Another method is to use a solution of sodium sulphate in water mixed with a solution of phenolphthalein (*in alcohol*) and water. With this solution the negative pole produces a pink color. This is what is used in the well-known pole tester, which consists of a glass tube, filled with a colorless liquid, into which are let in at each end. We add that the strength of these solutions may be varied widely with the same result

(12540) J. M asks: A curious thing happened in my neighbor's house. One day—it was just before noon—the lamp chimney exploded into small pieces, measuring, the largest, ½ inch down to less than ¼ inch. The lamp was not burning. The explosion made quite a report Can the SCIENTIFIC AMERICAN tell me what was the cause? A. The lamp chimney which went to pieces so suddenly and completely was strained in rapidly cooling, and probably was strained more in some directions than in others. The strain was finally so great that the glass gave way in the weakest place, and then the whole chimney went into bits Glass should be annealed very carefully by cooling very slowly to avoid such accidents Lamp chimneys sometimes break when the lamp is burning, because one part gets much hotter than the others.

(12541) J M M asks The Nebular Hypothesis assumes the cooling of hot bodies in space I have been unable to find any explanation consistent with the present theories of heat and of matter, as to what is, and as to how such cooling takes place, and what becomes of the heat lost by the cooling body. Obviously, it must either exist in space or be destroyed We cannot assume its destruction. The assumption that it exists in space in the form of heat waves in the ether leads to difficulties If this be so, only an infinitesimal portion of the heat lost would ever be picked up by any other body, and the total amount of energy in the material universe is and always has been constantly decreasing—hardly a safe assumption Nearly everybody knows how greatly the narrow and imperfect vacuum of a thermos bottle retards the loss of heat. The absolute and limitless vacuum of space must be far more efficient I shall be greatly obliged if you will clear up my difficulty, or still refer me to some discussion of the questions involved. A. No one can answer the question you ask as to the final disposition of the heat radiated into space constantly by the sun and all the heavenly bodies It is as unanswerable as that other conundrum, "What becomes of all the pins?" The law of the Conservation of Energy requires us to believe that it is received by other bodies which are colder and is absorbed by them for a time, to be radiated again, and so pursue a ceaseless round of radiation. Your statement as to the thermos bottle is not quite correct Radiation is not impeded by a vacuum. The little whirling radiometer shows that. A century ago or more, Rumford placed a thermometer in a Torricellian vacuum, such as is found in the barometer, and showed that it was immediately affected by external heat, by immersing the vacuum bulb in hot water. The vacuum in the thermos bottle prevents conduction and convection, the polished surfaces prevent radiation as far as it can be prevented. The thermos bottle thus becomes the best insulator for heat waves which we have. It is a modified Dewar bulb, such as is used for liquid air, made more durable than the usual Dewar bulb. You will find in our SUPPLEMENT 1883, price ten cents, a valuable article upon the "Heat Insulating Efficiency of the Exhausted Bulb."

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

Advertising in this column is 75 cents a line. No less than four nor more than 14 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

AERONAUTICS.

SAMBOO - Special Grades for Aeronautic Work up to 3 inches in Diameter. Reed, Rattan, split bamboo for insulation. Send for catalog, address, J. Dalton, Inc., 40 6th Avenue, New York City.

BUSINESS OPPORTUNITIES

STEAM ENGINE AND BOILERS.—All grades and sizes bought and sold. Corliss engines a specialty. Complete outfits. Write us your requirements. Bird of Machinery, Inc., Haverhill Street, Boston, Mass.

YOUR FACTORY AT TULSA will meet you the Middle West. Natural gas power only $7 to $8 H P per year. 36,000 population. Ample labor, materials. Great oil and coal fields. On large river. Your trunk railroads. Sixty-three thriving factories already. For further particulars write Industry, Bureau of Information, Tulsa, Oklahoma.

GOOD BUSINESS OPPORTUNITY.—For sale, a well established business, manufacturing and selling a specialty recently coming into general use. A nice, steady, interesting business which can be expanded indefinitely. No special manufacturing experience necessary, since present output is entirely contracted to be retained. This is an exceptional opportunity for a young man with $5,000 to $10,000. Address Box 72, Pittsburgh, Pa.

PATENTS FOR SALE.

FOR SALE OR ON ROYALTY—Patent No. 93,480, August 31, 1869. Quickly changing wrench. For further particulars, address J. J. Parsons, McCurtain, Okla.

FOR SALE.

SALESMAN MAKING SMALL TOWNS, just what you want for a pocket sideline. Something new, snappy and catchy. Write for samples and terms. Ground covered. R. Dakins Sales Mgr., 320 Sigel St., Chicago, Ill.

FOR SALE—Full set new series Scientific American, Vols. 1 to 10 inc., bound half sheep, good condition. Part of 2 vols. odd copies. For further particulars address, W. H. Jewett, Dover, Me.

REAL ESTATE.

CALIFORNIA LAND, planted and operated by experts, is a splendid investment. Many can best of all crops. Write Jackstraw Land Co., Arcadia, California. (Photos Gevaldon's Figs.)

OLD COINS.

MY NEW 80-PAGE COIN PRICING CATALOGUE just out Free. Buying coin catalogue sent on receipt of 15 cents in stamps. William Hesselton, Malley Bldg. New Haven, Conn.

HELP WANTED.

WANTED—A man or woman to act as our information reporter. Spare or spare time. No experience necessary. $20 to $50 per week. Write for free particulars. For particulars, Rules Association, 338 Association Bldg. Indianapolis, Indiana.

WANTED—A large motor car corporation wants to employ a young man who is familiar with advertising rate, and is competent to direct their distribution. Address, giving age, experience and present occupation. Only active candidates need write. Address Olds, P. O. Box 611, Detroit, Mich.

LOCAL REPRESENTATIVE WANTED.—Splendid opportunity assured right party to call on farmers. Must have car. Income guaranteed after learning our business thoroughly by mail. Former connection unnecessary. Splendid opportunity for ambitious, and willingness to learn a lucrative business. Write at once for full particulars. Address Manager, Box 1261, Minneapolis, Minn.

WANTED—Salesmen to sell Electric Refrigerators. Unusual opportunity for a man in your location to get started in a profitable business. Write today for full particulars. Address Box 1, Scientific American, 24 West 40th Street, New York City.

MISCELLANEOUS.

MOTORCYCLES CHEAP.—Send today for free catalog of new and used motorcycles. Also dealership solicited. Easy terms. Write today. Cycle Sales Company, 2nd & Main, Memphis, Tenn.

GENUINE Sahara is the purest way to make Big Money on Little Capital. One auto will yield $60 the week to $2 up. Write today for free booklet. Sahara Products Co., 1000 Sahara Bldg., Kansas City, Mo.

MAKE BIG MONEY showing Complete Line of Card Assortments. Proven money making values delivered on the spot. No set up necessary. Write for Free Sample Assortment. Write today. Imperial Card Co., Dept. 1, Chicago.

FREE—"INVESTING AND SPECULATING" Magazine. Send us your name and we will send you this magazine three months free. It tells how to make money in stocks and bonds. Write today. The Ticker Publishing Co., 42 Broadway, New York City.

CAN'T YOU REPRESENT US ON YOUR CALLS?—A responsible manufacturer of a complete line of Electric Refrigerators wants a man in your territory to represent them on their calls. Must be a man who can call on the best class of trade. Write us today. Address Box 2, Scientific American, 24 West 40th Street, New York City.

Artificial Life

(Concluded from page 372)

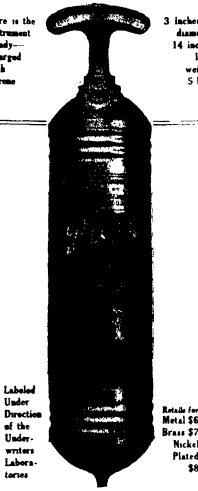
causes or conditions of development and growth. For the egg cell of many plants or animals is in a resting stage and can begin to develop, or, it can resume its activities, only after fertilization. Quite apart then from the relation to heredity, the process of fertilization must be somehow intimately related to the process of growth, the process of cell-division and those other processes that constitute the life of the organism. To produce artificial parthenogenesis is therefore to find the physico-chemical equivalent of a fundamental vital process.

For twenty years experimenters were able to make various physical and chemical agents do the work of the living sperm in causing the egg to begin its development, but the substitute was not quite complete, for the development in every case proceeded only a short way. A fertilized egg begins its development by a division of the nucleus into two halves, which form the centers of two cells. Each of these divides again, making four, these divide into two again, and so on, until (in very many species of animals) there is formed a hollow sphere of one layer of cells (Figs. 4 to 7). At this stage all the cells are practically alike. From this point on there appear various changes and differentiations in development. Most of the earlier experiments in artificial parthenogenesis did not carry the development of the young organism much beyond this stage. In recent years it has been possible to obtain artificially parthenogenetic individuals of sea-urchins and other organisms developed to a much farther stage, in some cases even up to the appearance of the adult form.

The first record of artificial parthenogenesis is that of the Russian zoologist, Tichomiroff, who in 1886 made the unfertilized eggs of silk worms develop by brushing them gently, or by placing them for a short time in concentrated sulphuric acid. During the following year Dewitz tried to induce development in unfertilized frog's eggs by treating them with corrosive sublimate, and reported successful results. But his experiments were repeated by Wilhelm Roux, who found that what Dewitz took to be early segmentation stages in the unfertilized frog-eggs were merely wrinklings on the surfaces. However, Richard and Oscar Hertwig observed the beginnings of segmentation under the influence of various poisons. In 1898, Kulagin experimenting with the unfertilized eggs of frogs and of fishes, obtained the beginnings of segmentation through the use of diphtheria antitoxin. These results have not been repeated, and their significance is not clear. Prof. Morgan used a variety of salts in the attempt to induce artificial parthenogenesis, and obtained a succession of nuclear divisions, but no true segmentation.

The most elaborate and fundamental experiments in artificial parthenogenesis are those by Prof. Jacques Loeb, begun in 1899. After familiarizing himself with the behavior of sea-urchin eggs under different conditions, and in relation to the sperms of several other marine animals, he began a series of experiments that have served as the basis for practically all subsequent work in this field. His first experiment consisted in raising the osmotic pressure of the water containing unfertilized eggs, by the addition of a quantity of common salt solution, and then returning the eggs to normal sea water. Although the results were different with different species, he obtained positive results with all of them. Yet the development of the eggs was not exactly the same as in the case of eggs normally fertilized.

One difference was that the fertilized eggs always formed a thin but distinct membrane before developing; the fertilized eggs developed much more rapidly than the parthenogenetic eggs; the fertilized eggs developed in about 100 per cent of the cases, whereas with the experimental eggs he obtained at first from 1 to 2 per cent. The larva of fertilized eggs had a smooth outline and swam near the surface of the water; the larva from the parthenogenetic eggs had a ragged outline—owing to the absence of a membrane—and clung to the bottom of the tanks (Fig. 3b.) From these differences it was included that the osmotic action of a hyper-tonic solution suffices to initiate not all of the effects of fertilization, but only some.



But later Loeb was able to induce the formation of a membrane in unfertilized eggs by the use of certain organic acids (monobasic acids of the fatty series, such as acetic, butyric etc.) Now the treatment of these eggs with the hyper-tonic salt solution after the formation of the membrane resulted in the normal development of the sea urchin eggs up to the so-called "Pluteus" stage (Fig. 2.) In these the rate of development and the surface-seeking habit were also as in the fertilized eggs.

When others tried to check this work by repeating the experiments in other laboratories, the results were widely divergent. Prof. Loeb himself then showed that these differences were due to the different chemical condition of the water at the various biological stations: the degree of alkalinity of the water is an essential factor. While in his earlier experiments he never had more than one egg in five develop, he was able to get 100 per cent after finding the relation of the alkalinity to the beginning of development. By means of an alkaline bath he induced the formation of membranes in the unfertilized eggs of a marine worm (*Polynoe*), and these were then induced to develop into normal larvæ, by means of osmotically active solutions; and by varying the concentration of the salt in the sea water, the rate of development could be regulated. By changing the alkalinity of the water, the sperms of star fish were so modified that they fertilized the eggs of the sea-urchin.

Step by step the results of these and other experiments were analyzed, and Loeb concluded that the first effect of fertilization, or the first essential for the resumption of activity on the part of the egg, is some liquefaction or hydrolysis (or both) of certain substances in the egg. But how this change was brought about was unknown. Hans Winkler thought that the sperm brings into the egg an enzyme or catalyzer. He reported to have caused unfertilized eggs to develop by treating them with an extract from sperms. Dr. Giles, of the College of Physicians and Surgeons (Columbia University) repeated Winkler's experiments and obtained only negative results. Using the unfertilized eggs of fishes, Cremer also had only negative results. Loeb showed that it was neither the addition of a positive catalyzer nor the removal of a negative catalyzer that started the segmentation. After the activity of the resting egg is renewed by either a sperm cell or by some one of the physico-chemical agents—which Morgan compared to a *stimulus*—there is needed something to make the nucleus grow and divide, this second factor Loeb considered to be something that will start the process of oxidation in a certain direction, since it is only through oxidation that nuclear matter could be made out of the reserve nutrients in the egg cell.

Yves Delage obtained results parallel to those of Loeb producing a membrane on unfertilized sea urchin eggs by means of acids and the subsequent liquefaction by means of an alkali. Later he was able to combine the action of the two factors in one solution by using tannate of ammonia. With this combination he was able to secure development without the presence of oxygen; his methods for eliminating oxygen, have, however, been criticized. He obtained also similar results with the eggs of starfish.

As a result of some of Loeb's work, the action of the chemicals used in these various experiments was compared to the action of ions, or of electric charges. To test the validity of the assumption that alkalies acted because of the negative ions (—OH) produced when they were dissolved in water, and that acids acted because of the positive ions (+H), Delage arranged an apparatus in which charges of electricity could be sent through the unfertilized eggs. He obtained a varying number of developing eggs as a result of sending first a positive and then a negative charge through the preparation. The following year, however, on repeating his

Fire in all its Destructive Horrors has at last found its master in

Pyrene

Pyrene is a combination of powerful gases in liquid form absolutely devoid of moisture, thus rendering it a non-conductor of electricity. When the liquid is subjected to a temperature of 200 degrees or more, it is instantly converted into a heavy, flexible non-poisonous gas blanket, which, surrounding the fire, excludes oxygen, and extinguishes the fire without damaging adjacent property.

Pyrene will not freeze at a temperature of 100 degrees below zero, does not deteriorate with age, thus eliminating cost of renewal, it does not corrode metals or injure varnished surfaces or the most delicate fabrics or materials. It is equally efficient on all classes of incipient fires, including chimney fires, cutam fires, grease and gasoline fires.

Autos, Garages and Motor Boats

Pyrene is recommended by the Automobile Underwriters Association of America and an approved Fire Appliance by the National Board of Fire Underwriters. Pyrene is approved by the U. S. Steamboat Inspection Service and by the Motor Boat General Insurance Agencies.

"Pyrene Liquid" is an absolute non-conductor and an extremely high insulator. It is, therefore, safe to use on fires caused by short circuits or on fires in and about electrical apparatus, regardless of voltage or amperage.

Arcs of 54 000 volts 9 amperes 220 volts 2 000 amperes, 600 volts 1 200 amperes, 2,300 volts 450 amperes, 20,000 volts 90 amperes have been successfully controlled without re-establishing or danger to the operator.

FOR GENERAL USE

"Pyrene" is especially serviceable in schools, factories, offices, public institutions, private residences, power stations and railroads. Its simplicity and the fact that it is not hazardous to life or property and can be used by man, woman or child, give it special claims on public favor.

experiments with improved apparatus, he concluded that neither electric charges nor electric currents have a direct effect in producing artificial parthenogenesis. The development of the unfertilized eggs in his first series of experiments he attributed to the action of acids and alkalies produced in the sea water under the influence of the electric charges From these results, and from other experiments in which he induced unfertilized eggs to develop through the use of various neutral chemicals — organic and inorganic — he concluded that the artificial parthenogenesis was always due to some specific chemical action upon some catalyzer, and a physical action upon the surface tension Delage succeeded for the first time in raising artificially parthenogenetic eggs up to the adult form Two of the individuals that had developed almost to maturity were both males

Parthenogenetic development was produced artificially by several investigators both in this country and in Europe, in the eggs of various species of marine worms, echinoderms and molluscs For example, Prof Lefevre of the University of Missouri induced normal development of the eggs of the worm *Thalassema mellita* by placing them for a few minutes in dilute acids

Six years ago Prof Michael F Guyer of the University of Cincinnati caused the unfertilized eggs of frogs to develop by injecting into them blood or lymph from adult frogs Although there was evidence that the white corpuscles carried on (or initiated) some special activities within the eggs, it would now seem that the beginning of segmentation may have been started merely by the pricking of the eggs with the needle of the hypodermic syringe For a few years later, Dr E Bataillon of the University of Dijon made the unfertilized eggs develop by merely stabbing them with a very fine point of glass or metal There was no introduction of any chemical substance, nor of electrical charge or "polarity" or anything else from the outside The shock alone seemed to be sufficient in some cases to start the segmentation, but in order to have the process continue there is needed the introduction of a second factor, which he believes to be a catalyzer, or activator Similar experiments made with the eggs of perch were without results, probably because the temperature of the water was not adjusted to the needs of the animals Experiments by Bataillon on the eggs of the lamprey eel, using salt water for starting the segmentation, were successful

Following up Morgan's suggestion that the physico-chemical effect of fertilization and the action of any agent used in artificial parthenogenesis were similar to a "stimulation," Dr Ralph Lillie set about to find what the common factor was in these cases He found that in the stimulation of a muscle as well as in the fertilization of an egg the first effect was an increase in the permeability of the protoplasm membrane Following up this lead McClendon tried various substances that cause the solution of red blood corpuscles and stimulation In all cases he obtained segmentation of the eggs but these substances had nothing in common from a chemical point of view, except the fact that they increase the permeability of the plasma.

From all the later experiments it is inferred that the first effect of fertilization is the loss of some substances This may be brought about by changing the permeability of the plasmatic membrane mechanically, chemically, electrically or by change of temperature; and this effect seems to be identical with the first effect in the stimulation of a muscle, or of a sensitive plant, or of a gland So far this agrees with the conclusions of Loeb But it is possible that the reason for the beginning of segmentation after the increase in permeability lies in the fact that this change brings about the removal of a substance—perhaps the product of protoplasmic activity—that interferes with further activity. A second stage, in fertilization as well as in stimulation, is accompanied by a change of electric potential at the surface of the egg—perhaps due to the introduction of new ions, in the case of fertilization, this condition may also be brought about artificially by means of mechanical, chemical or electrical agents Delage's sea-urchins and Bataillon's tadpoles give the most advanced stages in animals developed through artificial parthenogenesis. Whether it is possible to establish a mature generation of animals having only one parent, it is too early to say Histological examination may show that these animals contain the nuclear framework for only one-half of a normal animal's inheritance—as was found by Morgan to be the case in the non-nucleated egg fragments of sea-urchin in Boveri's experiment, and as was also found to be the case in the larvæ of *Thalassema* raised by Lefevre.

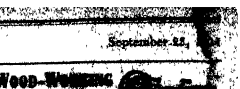
Whatever may be the limits for successfully inducing parthenogenetic development, these investigations must throw considerable light upon the nature of "living matter" and on the problems of heredity

New York State Barge Canal

(Concluded from page 277.)

paratively low divide in the vicinity of Rome, followed by another continuous descent, to the Hudson From this it will be seen that there are two critical points in furnishing a water supply for the canal The problem at the western end is readily solved by the abundance to Lake Erie, but throughout the history of the State canals, the question of supplying the Rome summit level has always presented more difficulties, and has led to the building of a chain of reservoirs among the hills to the south and within the Adirondacks on the north For the enlarged canal these existing sources are retained, and the two large reservoirs are added.

The work of building the dam and clearing the site at Delta, for impounding the waters of the upper Mohawk, about five miles north of Rome, is now about three-quarters done Across the greater part of the river gorge, 600 feet wide at its base, the dam has reached its full height of 100 feet above the lowest foundation When the gaps left for the river and an existing canal are closed, and the top of the dam is extended to its 1,000 feet of length, there will be formed a reservoir some four miles long and two miles wide at the base of its triangular shape, having an average depth of 23 feet and a capacity of about 20,750,000,000 gallons



The reservoir will be of value in regulating the flow of the stream below the dam The present low-water flow is from 100 to 150 cubic feet per second, and the maximum flood discharge, of which the record is about 8,200 cubic feet per second. It is estimated that the reservoir will limit all summer floods to a maximum of 2,500 cubic feet and winter floods to about 2,800 cubic feet per second

Large artificial lakes, built for the supply of navigable canals, are relatively few in number, and, if we ignore partially natural bodies of water, like the Indian River Lake, probably there are not in existence any comparable in size with those projected at Delta and Hinckley for the use of the Barge Canal However, most larger reservoirs have been constructed for other purposes The basin at Delta will hold less than one-twentieth part of the capacity of the Salt River reservoir, in Arizona, the largest in the world, and will cover little more than one-third the area of the Ashokan reservoir of the New York city water supply

Two Latin-American Aviators

THE names of Chavez and Moissant are still household words in Peru and Central America, respectively, though for somewhat different reasons. A writer in the *Deutsche Zeitschrift für Luftschiffahrt* tells of the diverse way in which the career of these martyrs of aviation have impressed themselves upon the imagination of Latin-America.

All Peru takes pride in the heroic and disastrous feat of Chavez. The remains of his aeroplane have been transported to Lima, and placed in a prominent place in the National Museum, in the hall where hang the portraits of the 89 Spanish viceroys. Pizarro and his successors. In the enthusiasm evoked by his transalpine flight an aviation league was founded in Peru, and a Peruvian-born employee of the Blériot works—one

AGENTS

I want a good man as local agent, or as general agent, for a number of counties. Men in every territory to take hold of this wonderful opportunity. An exceptional chance to make good. Irresistible selling proposition. Everybody enthusiastic. Actual experience not necessary. 100% profit. Make

$45 TO $90 EVERY WEEK

No experience is necessary, but I want men, young or old, who will do their very best, who will work for results and who will follow instructions. I am organizing my selling force now, and I want you to begin at once. Write for complete information today.

J. W. Carpenter, a new man, started ten days ago; first report, $70 sales in six days, first order 30 Amos droppers. Another (Alison Pardy) took 27 orders first day out (sworn statement); profit $40.50—20 orders next day. Most of our men have started without experience as salesmen. The Never Fail Dropper caught on so tremendously that they make more money than they ever dreamed of. You can do the same. Act. Investigate. Get busy. No risk is needed. Just show it was the cropper and he wears it immediately. No modern invention has received such unanimous welcome. Remember, the Never Fail is absolutely up-to-the-minute, guaranteed unconditionally to suit and comfy user for life.

This is a new proposition. A up date automatic razor stropper—absolutely guaranteed to sharpen to a keen, smooth, velvety edge any razor—safety or old style—all the same. Hundreds say and every blade automatically. Just a few seconds will put it in perfect and better shape than a fine cooling, soothing, satisfying shave than can any expert hand operator, no matter how carefully he works. Men are eager to buy it. Women love it for presents to men.

The possibilities are unlimited. We absolutely prepare you on how to start at once and make a great success for yourself and us. Investigate. Don't delay. Territory is going fast. Write today, and give the name of your county.

Address, Secretary, THE NEVER FAIL CO.
1134 Colton Building, Toledo, Ohio

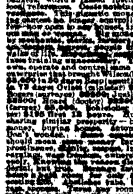
Maxim Silencer

Don't go in the woods without one!

The .22 calibre Silencer enables you to shoot small game and hold target practice without frightening off big game. Attaches immediately to any .22 calibre rifle.

Silencers are also furnished for all calibres above .22. Reduce recoil—improve marksmanship.

Write today for new Catalog, just out.



MAXIM SILENCER, Hartford, Conn.

WIN THIS $1200.00!

Thousands Already Won—Going on Daily

TEN PEOPLE GET $40,000

They Tell You How to Win.

LISTEN! Sizemore(Kans. photog'ph'r) originally received $1800 a month, $51.50 in 14 minutes, $4000 in 10 days, Kendall (Mich. farmer) $60,000 in 3 weeks, Bergette (N. Y. tel. grapher) $100 daily, Mrs. Smith (Ohio plumbing, 1st woman admitted to trade) seven passengers, statements, judges, lawyers, women, children, $1000 in 3 days, Cotton (Ga. farmer) $1000 in 3 days, Cotton (Ga. farmer) $1000 in 3 days, Cotton (Ga. farmer)

Its third year—and HUPMOBILE demand unabated

Runabout $750, F. O. B., Detroit

Equipment includes top, windshield, gas lamps and generator, three oil lamps, horn and horn. All cycles have 30 H. P., 4 cylinder motor adding gear transmission, Bosch magneto. Coupe, $1150. Torpedo, $850

Runabout Fully Equipped $750 F. O. B. Detroit

Hupmobile

Touring Car Fully Equipped $900 F. O. B. Detroit

GUARANTEED FOR LIFE

Now, in its third year—amid a bewildering distraction of new models and new prices—the Hupmobile is bought as eagerly as it was in its first season

Then it was a sensational novelty—a car unheard of at a price unheard of.

Today its place is firmly fixed. Its hold has grown stronger and stronger upon those level-headed buyers who always asks and always get the most for their money

Hupmobile demand has been steady and consistent through two seasons and well into its third

Public confidence was gained at the outset, and has been held through the keeping of faith and the giving of generous value.

For weeks our factory has been under the supreme test of working day and night in order to produce cars rapidly enough to keep pace with the volume of orders.

The Hupmobile occupies this unique position because it has been true to itself and true to the people

It has gone on being better and better until now—with more than $100 added in improvements and almost as much more in equipment—it is as extraordinary a car as it was three seasons ago

At this time we wish to call attention particularly to the Hupmobile Coupe—which has been aptly termed a "baby grand limousine"

It has gone a long way toward displacing the old idea that an enclosed car is restricted to town use.

It was only recently that three residents of Elgin, Ill., toured in a Hupmobile Coupe from Chicago to Minneapolis, via Mankato, Minn—more than 500 miles—without trouble of any sort and showing an average of 25 miles per gallon of gasoline over country roads and hills. Last November a physician of Hammond, Ind., drove his coupe home from the factory in Detroit

HUPP MOTOR CAR COMPANY, 1238 Jefferson Avenue, Detroit, Michigan

JUST PUBLISHED A New and Authoritative Book

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING, B.Sc., A.M., C.E.

CRITICISMS

"The first treatise upon aviation which we have seen which may be styled really complete. . . . . Actual aeroplane designing is the central theme of the volume. . . . . The prominent types are exhaustively compared. . . . . The illustrations are a notable feature."

—*Rochester, N. Y., Chronicle.*

"A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplane. . . . . Presents in a compact shape the substance of aerodynamic theory. . . . . Easily comprehensible to the reader who can concentrate his attention. . . . . It is the most scientific popular book on the aeroplane that we have come across so far."

—*New York Sun.*

"Many writers have failed to realize the demand which exists for aero literature in which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the entire subject. For a writer to steer a straight course between the mazes of trigonometry on the one hand, and the superficialities of mere discussion in a popular vein on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who can sufficiently divorce himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and information of the less erudite seeker after knowledge."

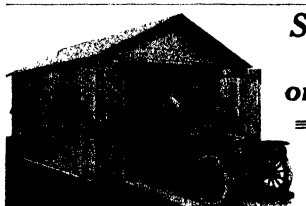
—*Phila. Inquirer.*

"Students learned in aerodynamics and laymen ordinarily interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have realized the future of aerial navigation, and desire a work treating solely of the heavier than air machines written by an acknowledged expert and with no hobbies hidden in the theories."

—*Boston Journal.*

"While enthusiastic in his interest as becomes one who has written so superb a volume, Mr. Loening is also rigidly accurate as the most exacting scientist could demand. Here is a work which is at once a history and textbook which may be depended upon for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once new and authoritative with reference to the entire subject and that it is practical in the highest degree is the just praise due to this volume."—*Buffalo News.*

"Mr. Loening has written, in fact, for the man who wishes to apply practically the experience that has already been gained."



—*New York Times.*

12mo. (6x8¼ inches) 340 Pages, 270 Illustrations. Attractively bound in cloth.

Save Winter Storage on Your Car

ORDER NOW a

Pruden System Fire-proof Garage

Use next winter's storage bills to *pay half* the cost of a **Pruden Garage** and have your car always handy and safe. Many owners use their autos all winter long, keeping them in a **Pruden**, without heat

Unit-Built Portable Handsome Durable as Masonry Low Cost

Pruden System Construction is entirely original with us and utterly unlike anything else. It gives you *fire-proof* protection in a building as handsome and substantial as masonry, at *one-third the cost*

Here's the only portable garage that is wholly fire-proof. No wood in a **Pruden**. Entirely built of handsomely embossed *galvanized steel units*. You erect it in a few hours with screw driver and wrench, and as easily take it down. **Pruden** buildings *last a lifetime*, never need repairs, do not depreciate in value and are *rigidly guaranteed*. You simply can't realize how different and how perfect the **Pruden** is in every detail until you get all the facts

Mail Coupon for Catalog Today—

The Metal Shelter Company

WOOD DISTILLATION for manufacturing ALCOHOL and other products of the process

¶ Profits from refuse wood and sawdust are in reach of any one who will locate near a sawmill. The Scientific American Supplement files contain a series of valuable articles on this topic which are contained in the following numbers:

1610—A General Review of the Subject of utilizing wood waste, and the uses to which the wastes may be put.

1684—The "steam" and "destructive" distillation processes, and names the numerous products obtainable from the complete operation.

1681—Distillation of soft wood, and gives the proportions and quantities of each product obtainable, and the various processes used.

1723 and 1724—The general subject of the utilization of wood wastes, giving all the products by a clear and valuable diagram showing their relations to each other, and many illustrations of apparatus.

1592—The manufacture of wood alcohol by a German process which first converts sawdust and scraps to glucose and then to alcohol, leaving the residue of the wood with 75% of its heating value, and in condition to briquette without a binder.

1789—Prof. Rattan's article on the manufacture of wood alcohol, a very comprehensive discussion.

1643—Dry distillation of Beech and other hardwoods comparing European and American methods, and giving the quantities of products obtained.

1335—Charcoal manufacture in Germany, with complete recovery of by-products, their description and uses.

1472—"Distillation of Pine Products" refers especially to turpentine manufacture, but covers the by-products as well, and gives information of the profitable nature of the business.

1851—Refers to acetic acid, wood spirit and acetone from distillation of wood, and gives a good description of the necessary apparatus, and particularly of the points to be observed in operating the plant.

1736—Production of Alcohol from Cellulose, how wood and wood products may be used.

Each number of the Supplement costs 10 cents. A set of papers containing all the articles above mentioned will be mailed for $1.20. Order from your Newsdealer or from us.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are suitable, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Ramming of the "Olympic"

SOME years ago, in the merry scramble to get home quickly from one of the America cup races off Sandy Hook, the steamer "Monmouth" found herself overlapping the yacht "Corsair" as these two speedy craft were nearing a turning buoy in the old Gedney Channel. The writer, who was aboard the "Monmouth," noting that the two vessels, in the wish to make a close turn at the buoy, were drawing very closely together, was watching the action of the bow wave and wash and wake of the one vessel upon the other. When the "Monmouth" had drawn half her length ahead of the "Corsair," the latter sheered slightly toward the "Monmouth," apparently with the intention of swinging in closely under her stern, preparatory to turning. After the "Corsair's" bow had approached slowly to within a certain distance of the "Monmouth," the yacht suddenly closed in and struck the "Monmouth." The blow was delivered as swiftly as though the helm had been put hard over for the purpose.

It was evident to the writer that the lateral force which swung the "Corsair's" bow so quickly against the "Monmouth" was due to the lateral inflow of the water, displaced at the bow of the "Monmouth," as it closed upon her stern. Naval Constructor D. W. Taylor recently investigated this matter in the course of some interesting experiments in the model tank at Washington, in which he determined the action of vessels upon one another when they are steaming in close proximity and upon parallel courses. This investigation proved that under such circumstances any two ships have a strong tendency to close in upon one another. Judging from the cabled reports, the ramming of the "Olympic" was due to conditions similar to those above referred to. The cruiser "Hawke," a relatively insignificant vessel of 7,000 tons displacement, was steaming abreast of and in rather close proximity to the "Olympic," when the cruiser's navigating officer decided apparently to pass under the stern of the big ship. He probably put his helm over to what would have been the correct amount to enable him to execute this maneuver safely in undisturbed water; but as soon as his bow swung over into the wash of the steamer the "Hawke" appears to have been drawn against the "Olympic," exactly as was the "Corsair" against the "Monmouth."

The disaster serves to show that there is safety in size. The ship which did the ramming weighs about 7,000 tons, the "Olympic" at the time of the disaster weighed probably about 60,000 tons. Judging from the speed of the "Hawke," she struck a blow which probably would have sent a ship of average size to the bottom, but so huge is the Olympic" that the enormous rent which was torn in her skin-plating and the flooding which followed seem to have had but little effect upon her stability. She was never at any time in serious danger. The extra strength and stiffness of her bulkheads rendered them amply sufficient to withstand the strain of flooded compartments. It is probable that if the accident had happened at sea and in rough weather the big ship would have made her way comfortably back to port.

The Radium Engine

IN his remarkable British Association address, Sir William Ramsay stated that the disintegration of radium liberated three and one-half million times the energy available by the explosion of an equal volume of detonating gas—a mixture of one volume of oxygen with two volumes of hydrogen. He pointed out that the major part of this energy comes apparently from the expulsion of particles (that is, of atoms of helium) with enormous velocity. "Suppose," says Sir William, "suppose that the energy in a ton of radium could be utilized in thirty years instead of being evolved at its invariable slow rate of one thousand seven hundred and sixty years for one-half disintegration, it would suffice to propel a ship of 15,000 tons, with engines of 15,000 horse-power, at the rate of 15 knots an hour, for thirty years, practically the lifetime of the ship. To do this actually requires one and one-half million tons of coal."

Here is a statement of radium's possibilities that may well give a steam engineer pause. Why bother about thermo-dynamics, about Carnot cycles, about the relative merits of turbines and reciprocating engines? Why not develop the radium engine and conserve our coal supplies, and manipulate ounces of radium instead of tons of coal? At one fell blow all our elaborate coal-conveying machinery disappears, and with it roaring furnaces, the blackened faces of stokers, and all the sooty paraphernalia that the word "steam engine" stands for.

The possibilities are far more romantic on paper than in actual fact. In the first place, where are we to get a ton of radium? Sir William himself in times past has placed the total supply of radium in the world, in laboratories, at much less than a pound. Physicists and chemists have time and time again pointed out the enormous personal risk involved in handling even a half grain of comparatively pure radium. Bacteria, insects and even mice, we believe, have actually been killed by radium rays, suitably applied, to be sure. What will be the effect upon a man sitting in a room containing, let us say, ten pounds of radium? Would he ever emerge alive? Obviously, the mere difficulty of handling so terrible a substance imposes problems far more difficult of solution than those which the old steam engine ever offered.

Assuming that we really had a safe method of handling a large quantity of radium, how are we to make its energy available in practical form? Some totally new type of prime mover must be developed, some contrivance which will render it possible for electrons hurled into space with the speed of light to do their work.

Then again there is the subject of materials to be considered. Radio-active substances are no respecters of ordinary containers. The particles projected from radium permeate most substances with comparative ease. To confine them would be a far more serious task than the insulation of a steam pipe.

Stupendous as the problem is, who shall be bold enough to say that it will never be solved? After all, is the utilization of the enormous energy contained in a half grain of radium any more startling than the transformation of the energy sent up in a shovelful of black coal? If the radium engine ever does come, it will simply be another instance of the triumph of mind over matter.

From the Complex to the Simple

A MARKED step was taken in the simplification of prime movers when Watt's cumbersome beam engine, with its ingenious but elaborate parallel motion, gave way to the present standard reciprocating type, with only piston rod, cross head and connecting rod interposed between piston and crank. An even greater advance toward ideal simplicity occurred when, after years of effort by inventors to produce a practical rotary, Parsons brought out his compact, though costly, turbine, in which the energy of the steam is developed on a zigzag path through multitudinous rows of fixed and moving blades.

And now comes Mr. Tesla with a motor which bids fair to carry the steam engine another long step toward the ideally simple prime mover—a motor in which the fixed and revolving blades of the turbine give place to a set of steel disks of simple and cheap construction. If the flow of steam in spiral curves between the adjoining faces of flat disks is an efficient method of developing the energy of the steam, the prime mover would certainly appear to have been at last reduced to its simplest terms.

The further development of the unique turbine which we describe elsewhere will be followed with close attention by the technical world. The results attained with this small high-pressure unit are certainly flattering, and give reason to believe that the addition of a low pressure turbine and a condenser would make this type of turbine as highly efficient as it is simple and cheap in construction and maintenance.

Lessons of the Transcontinental Flight

ON September 12th and 13th two biplanes, a Wright, piloted by Robert G. Fowler, and a Curtiss, driven by James Ward, left San Francisco and New York, respectively, in an attempt to fly across the continent in less than thirty days. Under the rules the flight must be finished by October 10th. In view of the automobile record of fifteen days, the flyers thought they had ample time, even allowing for accidents. Special trains with several extra machines were reported to be in close pursuit, and if any accidents were met with, it was expected that repairs would be promptly made.

Aviator Fowler made an excellent start on September 12th, circling over the Golden Gate and San Francisco Bay and making his first stop at Sacramento. After replenishing, he continued on to Colfax in the foot-hills of the Sierras. He was just beginning the long climb of more than 5,000 feet to the summit (7,018 feet) when, at Alta, the control wire of the vertical rudder broke and he came fluttering down in spirals. The machine was badly broken, but Fowler fortunately was not seriously injured. A delay of ten days occurred before the biplane was ready to fly again.

The start of Ward from Governor's Island on the 13th seems to have resulted in the bad luck generally attributed to that number. Little Ward is the youngest and lightest aviator of the transcontinental race trio. After losing his way at the start, he was delayed by motor troubles of various kinds, chiefly by lack of lubrication, due to faulty operation of the oil pump or leakage of oil from the crank case. Even after testing his new motor thoroughly on *terra firma*, he was unable to fly many miles before he was forced to alight for further repairs. In alighting he hit a tree and smashed his machine again, which caused him to abandon the race.

An excellent start was made by Calbraith P. Rogers on Sunday, September 17th. Rogers, who like his brother, Lieut. Rogers of the Navy, flies a Wright biplane, departed from Sheepshead Bay at 4:38 P. M. on Sunday. He flew directly across Brooklyn and New York, crossed the Hudson opposite Madison Square, and picked out the Erie tracks by means of white streamers that had been placed on the ground along the line of the railroad. He flew without a stop to Middletown, N. Y., where he arrived 1¾ hours after his start from Sheepshead Bay. The total distance covered was 84 miles, which corresponds to an average speed of 48 miles an hour. In starting from the race track at Middletown the next morning, Rogers came to grief and smashed his machine. The place from which to start was very restricted and the machine was unable to lift the heavy six-foot-four aviator quickly enough to avoid a large willow tree directly in his path. Rogers skillfully turned aside and cleared the tree, only to hit the top of another tree, which upset his machine and tumbled it to the ground. Rogers landed upon his feet after a fall of 30 feet or more and was uninjured, but his aeroplane was badly smashed. In four days, however, he had secured new parts and reconstructed his machine, and on September 21st, at 2:29 P. M., he left Middletown. With a strong, favorable wind to aid him, he covered 80 miles or more in 1 hour and 6 minutes, and alighted at Hancock at 3:35 P. M. The next day he covered 250 miles in all, but got off his course at Susquehanna and made a detour to Scranton, Pa., before reaching Binghamton. He was over 6 hours in flight and finally reached Elmira.

The results of the race to date have demonstrated that training in cross-country flying is essential in order to make a good performance in a race of this kind. Rogers' accident was due to faulty judgment, but besides this he wandered from the course owing to his inexperience in cross-country work. The accident which happened to Fowler is one which should not happen to any well-made aeroplane. This is not the only time that a control wire has broken on a Wright machine while in flight. The delay caused by the breakage of his rudder wire may cost Fowler the race. He is indeed lucky that he escaped without serious injury, as the vertical rudder is considered by the Wrights to be quite essential to their system of control. Using the warping alone Fowler managed to descend in spirals, but he was unable to pick a suitable landing place.

Power from Sunshine

An Installation of Sun-Power Plant

THE direct utilization of the natural forces in the development of power suitable for human activities has been for centuries a matter of continued scientific research.

To a limited extent these forces have been used from the dawn of civilization in the common forms of the windmill and various types of water-driven motors. It has not, however, been hitherto possible to practically utilize the central dominating forces of nature—the sun's heat—in any direct manner, though obviously all power generators are dependent upon this great source for their existence.

For many years engineers and physicists have been occupied with this problem; notably Ferry, Millochan, Mouchat and Tellier in France; Gilntner and Althaus in Germany; and Langley, John Ericsson, and Wilsie in America. These experimenters based their efforts either upon the use of lenses or mirrors to concentrate the sun's rays upon a small surface, or upon the heating of fluids of a low-boiling point, with subsequent power generation from the vapor under pressure. It has always been attempted to create vapor at high pressure, and then utilize this in the ordinary engine, but with the high temperatures involved, the losses by conduction and convection are so great that the power produced was of no commercial value. Where lenses or mirrors are used, the primary cost of the lenses, and the apparatus necessary to continuously present them toward the sun, have rendered them impracticable

Where fluids of low boiling point, such as ether, sulphurous acid, and liquid ammonia were used, the results were of little value by reason of the inherent inadequateness of these fluids as power generators.

A sun-power plant, in order to be practicable, must possess, first, high efficiency, low cost of installation and maintenance; well-marked length of service, and should not require specially trained mechanics for its operation

In order to be efficient, it is not necessary that the plant generate continuously, inasmuch as the great value of such a plant lies in its use as an irrigation apparatus; it is only necessary that the plant run about eight hours daily. It must, however, consist of units which may be assembled to produce a power plant of any required size, the larger the plant the greater the efficiency It is entirely practicable to produce a sun-power plant in this manner up to 10,000 horse-power and over. An ideal plant must be subject to little accident; hence, it must lie near the ground in order not to be affected by storms and winds. Each unit must be repairable without stopping the operation; construction must be simple and easily understood by the ordinary steam engineer; and wear and tear must be reduced to a minimum.

The first cost of a sun-power plant to be practical, and of commercial value, must be sufficiently low so that the interest on the investment does not make it unprofitable. This is the rock on which, thus far, all sun-power propositions were wrecked. It is not necessary that the cost of the sun heat absorber shall be as low as that of a steam boiler and fitting of the same power. The cost of the plant described herein is twice that of the ordinary steam-power plant of the same size. This price is sufficiently low, however, so that even if the extra fuel is taken into consideration, the fact that after installation no fuel is required, is such an enormous advantage as to entirely offset the increased cost, and in addition cause great profits.

Some ten years ago the writer became interested in the problem of obtaining power by absorbing the sun's rays. It was found, by experiment, that if a vessel were so arranged that the sun's rays could impinge upon it, and if all heat losses by conduction, convection and radiation were prevented by a theoretically perfect method of insulation, the temperature within the vessel would rise certainly to a thousand degrees Fahrenheit without any attempt being made to concentrate the rays of the sun. For commercial purposes it is impossible to secure any form of insulation which would even approach the theoretical. Commercially, the main object is to produce practical power at a minimum cost, and this has been done by the use of well-known and cheap forms of heat insulation

Were no steam made in these vessels, as they are arranged in the present plant, the temperature therein would go up to 350 deg. F. in latitude 40 north, possibly easily to 450 deg. F near the equator. The production of steam at atmospheric pressure, however, keeps the temperature in the vessels down to 212 degrees, and whatever excess of heat is produced by the sun's rays over and above that lost, is converted into steam, and may therefore be utilized

The experience of additional years will, no doubt, lead to designs considerably better than this first attempt on a commercial scale. Sun power must go through the same long and gradual course of development that has brought other forms of mechanical power to the present high plane of efficiency but the principle will remain fundamentally correct

With this idea in mind the first Shuman generator was built. It consisted of a wooden box covered by two layers of glass, between which was a small air space, and in the box was placed a miniature ether boiler. This apparatus was exposed to the sun's rays, the ether distilled, and the amount of heat which might be absorbed was determined. As an experiment, a small toy engine was successfully run with this original apparatus. A second generator consisted of a 2-inch steam pipe 16 feet long, insulated at the bottom, and inclosed in a box covered by a double layer of glass. Here again ether was distilled, and the number of heat units absorbed were determined. A third type of power plant was composed of a bed of water pipes properly insulated against heat loss, the unit being 18 x 60 feet, and the motor being an ether engine. With this apparatus 3½ horse-power was obtained. With the knowledge so gained, the present generator, to be described below, was gradually evolved.

The sun-power plant in its present development consists of the absorber, a low-pressure steam engine, condenser, and auxiliaries

The absorber, in a general way, is composed of a series of units, each containing a flat metal honeycomb water vessel rectangular in shape, and resembling closely a large waffle. This vessel is inclosed in a flat wooden box covered with two layers of glass having a 1-inch air space between them, and having the under surface of the box insulated against heat loss downward by a 2-inch layer of regranulated cork and two layers of water-proof cardboard.

The boxes are mounted on supports which elevate them some 36 inches above the ground, and which permit them to be inclined perpendicular to the sun at the meridian. These adjustments of the inclination need only be made about once in three weeks.

Plane mirrors of cheap construction are mounted on two sides of the boxes in order that more rays of the sun may be absorbed and reflected upon the surface of the water vessel. This latter is connected at one end to a feed pipe from the water supply, and at the other end to a steam pipe. The steam pipes from the various units are connected together and empty into a main 8 inches in diameter in the present plant, which conveys the steam to the engine

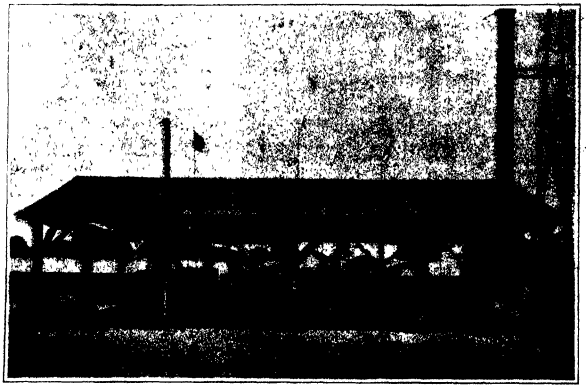
The engine is a new type low pressure, reciprocating steam engine of great steam economy. Connected with it is a condenser of ordinary type and auxiliaries such as may be found in any condensing plant. The water from the condenser is pumped back into the absorber, thus insuring a continuous closed circuit whose only water loss is from accidental leakage, which is carefully guarded against

The power of this first plant is used for pumping water by means of a reciprocating steam pump of the ordinary type and whenever the sun has shone during the past six weeks, this plant has pumped water successfully and practically. The capacity of the present plant in this latitude, is 3,000 gallons of water per minute, lifted to a height of 11 feet

From actual tests made in Philadelphia in August, 1911, it was found that from the absorber of 26 banks of units, each containing 23 single units and having a light absorptive area of 10,296 square feet and an actual area of 5,148 square feet there could be developed during eight hours 4,825 pounds of steam. The power produced was much lower than normal to the plant, as it was built for tropical use and was entirely unfitted for commercial work in northern latitudes

It is found by observation that the steam generated in a sun-power plant is reduced largely by humidity and the presence in the air of smoke haze etc. It follows, then, that the efficiency will be greatly increased when the apparatus is tested in a dry climate free from atmospheric impurities attendant upon proximity to a large city. The plant was set up at Philadelphia not because it was considered to be a commercial thing there but because the necessary experimenting with a new plant thousands of miles from home would have been exceedingly expensive. Within a month or two this plant will be taken down and erected in Egypt. This can be conveniently done, as the entire heat absorber is practically portable

Again the loss of heat by conduction and convection in northern latitudes is enormous. If the present apparatus is placed in an average air temperature of 100 deg. F., such as obtains throughout all equatorial regions it is safe to assume that the power will be multiplied three-fold



Having described the mechanism of the sun-power plant, it remains to discuss the opportunities for its use. The immediate opportunities for sun power are in those regions in the tropics where the sun practically shines throughout the year, and fuel is very expensive, coal costing in some localities $30 per ton

There is room now for at least half a million horse-power in such tropical fields as the nitrate district of Chile, the borax industry in Death Valley, and for general purposes in places where the outside temperature runs from 110 to 140 degs. F

As an irrigation engine there is no limit to the amount of power that can be practically utilized, and for this purpose the conditions need not be so very favorable as those mentioned above. Throughout most of the tropical regions *sun power will prove very profitable in irrigation*. One advantage of the sun power, or, in fact, of any condensing plant for irrigating purposes, is that the water used for the condenser costs nothing, as the main output of the engine can be passed through the condenser first be-

fore entering the irrigating canals for distribution.

The interior of Australia was, at one time, a fertile country, as is evidenced by the fossilized trees. Here is an area of some 600 miles in each direction which is entirely valueless. During a drought there have been times when one-third of the sheep raised on the margins of this desert died from thirst, causing great financial loss. In this locality the sun shines with an intensity sufficient to produce an average daily

Front view of engine, auxiliaries and water pump.

temperature of 100 to 140 degs F. The occasional rains nourish the sparse vegetation necessary for sheep, which are watered from wells driven in the ground and pumped, generally by horse power, very often by hand, and sometimes by means of fuel oil, which, by the time it reaches its destination, brings the coal equivalent up to some $20 per ton. By building sun engines in this region, and pumping from the always present underground water which in this region lies at a depth of from 15 to 40 feet, this country can be made productive and valuable.

Throughout Eastern India and Ceylon many thousands of square miles of farm land can be improved three fold by mechanical irrigation. Hand pumping is mainly the present form of irrigation used.

In Egypt agriculture depends entirely upon irrigation furnished by the River Nile through its periodic overflow. The English government built the Assuan Dam at an enormous expense, and widened the irrigable area about half a mile on each side of the Nile, thus adding greatly to the tillable portion of Egypt. Of course, when the Nile is in flood infinitely more water than necessary is furnished, but the demand is for a supply which can be depended on from day to day, especially at seasons of low water. This supply at present is furnished by the hand labor of some 100,000 fellaheen who pump by means of the shadoof method. One sun engine, such as is now erected in Tacony, will do the work of about a thousand of these laborers.

Throughout Arizona, Nevada, New Mexico and Southern California there is room for any amount of power for irrigating purposes alone. These States show an average of 90 per cent sun light, and the cost of fuel is practically prohibitive in most of this region.

To summarize all of the above statements it may be assumed that 10 per cent of the earth's land surface will eventually depend upon sun power for all mechanical operations. Given inexhaustible power, which is, of course, always obtainable from the sun, and utilizing the nitrogen in the air for fertilizer in the form of nitrates and such compounds as calcium cyanamide, the human race will be enabled to draw directly on the source of all life for power and sustenance.

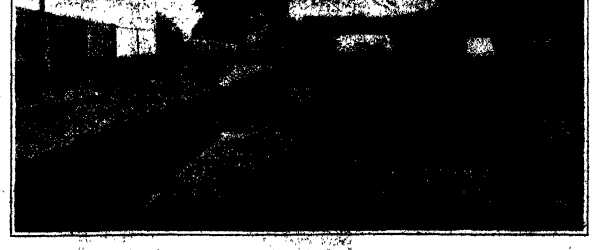
A question of paramount importance in the possibilities of a general use of sun power is the cost of the apparatus.

In the Shuman type of sun-power plant, the engine, condenser and auxiliaries are similar to those in daily use by steam plants and may therefore be eliminated from comparison; leaving the absorber and the ordinary steam boiler alone to be compared. It is found that at this time the initial cost of the sun-heat absorber in question is about double that of a first-class boiler plant of equal power.

The great economy occurs in the item of fuel. In districts especially suitable for sun power the cost of coal, or its equivalent, is usually very high, the price ranging generally from $10 to $30 per ton. To offset this, no fuel at all is required by the sun heater.

In the matter of maintenance and repairs also the advantage lies with the sun power. It is estimated that the repairs should not be in excess of 5 per cent per year on the initial cost, inasmuch as the apparatus works at low temperature, while the ordinary boiler requires flue gases up to 2,500 degrees. This cost of the parts must manifestly be much greater in the latter form of power plant.

Many parts of the sun-power plant, such as the metal heaters, piping, foundation and insulation, are practically everlasting, barring accidental breakage, the only item of repair being the wooden frames and glass covers, and it is found that after an installation of glass has once been tested out by the heat, and the badly annealed sheets replaced, the remainder will last for years. This was evidenced by the small 18 x 60 feet heater in operation for three years in Philadelphia. There was a replacement of about 10 per cent necessary during the first three weeks; thereafter the heater ran three seasons and only two or three sheets of glass needed replacement, these being accidentally broken.



There is now being tested out a celluloid-like material having all the necessary properties of glass and being flexible and capable of manufacture in large sheets. The use of this substance will not only greatly reduce the cost of installation of sun-power plants, but will make repairs a factor of but slight importance.

It may also be said that the large area covered by the sun-power plant would add greatly to the expense, but inasmuch as these plants are intended for use where the cost of land is very low, such criticism is not valid.

The future development of solar power has no limit. Where great natural water powers exist, sun power cannot compete; but sun-power generators will, in the near future, displace all other forms of mechanical power over at least 10 per cent of the earth's land surface; and in the far distant future, natural fuels having been exhausted, it will remain as the only means of existence of the human race.

The Current Supplement

THE rumor of the birth of synthetic rubber makes us look with renewed interest at those industries in which India rubber is worked up into various articles. A review of the Present Status of the Rubber Industry forms one of the principal topics in the current SUPPLEMENT, No. 1865.—The fifth instalment of Prof. Turner's article on The Great Star Map continues his discussion of the subject of star positions.—The length and character of wood fibers is a subject of interest both to the botanist and to those who carry on industries using wood as a raw material. The subject is discussed in a brief illustrated article.—Every now and again a seemingly new disease becomes fashionable. A case of this kind is appendicitis, which for some years past has sprung into remarkable prominence. The question naturally arises, Is it really a new disease, or if not, how came it to escape our notice until recently? The discussion of this question by a French physician has appeared in *Cosmos*, and is reproduced in this paper.—A striking new development, along the lines of Lodge's classical experiments on Fog Dissipation, comes to us from California, where Prof. Cottrell has successfully applied electricity for the precipitation of fumes occurring in manufacturing processes. The report of his work, abridged from the *Journal of Industrial Chemistry*, is incorporated in the current issue.—The economies resulting from the use of fitting nozzles in foundries are expounded by H. F. Stratton.—A simple electroplating apparatus is described.—A. Emerson tells of a newly discovered portrait of Constantine the Great.—Two short articles are devoted to phases in the plant industry, the one on the recovery of useful products from willow bark, the other on a device for testing cereals for their resistance to disease.—The second instalment of F. P. Valentine's valuable paper on Problems in Telephone Traffic Engineering appears in this issue.

Safety valve blowing off at one-half pound above atmosphere.

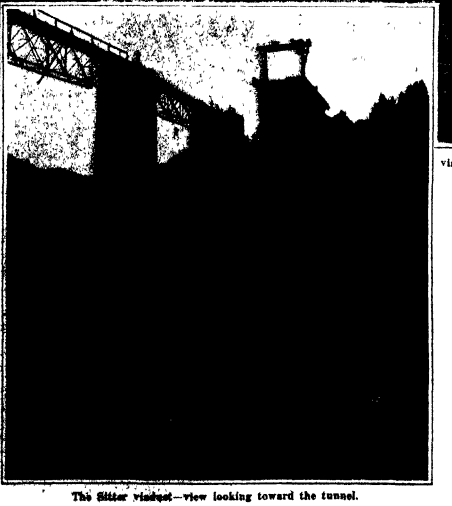
PRESSING THE SUN INTO SERVICE

The Sitter Viaduct

A Remarkable Swiss Engineering Work

By the Paris Correspondent of the Scientific American

ONE of the most remarkable works in Switzerland, noted for its wonderful engineering structures, is the Sitter Viaduct. This is indeed the highest structure which the Swiss engineers have yet built. The viaduct lies on the line of a newly-built railroad known as the Bodensee-Toggenburg line, and is situated on the section of railroad lying between St. Gall and Watwil. It is built in a very picturesque site, where the Sitter torrent after joining the Urnasch stream, has worn down a deep cutting between the rocky faces of the adjoining heights. The railroad lies on the higher level, whence the need of a long viaduct in order to span the valley.



The great Sitter viaduct—eastern aspect

The total height of the viaduct is 1,180 feet. There is a middle space of about 400 feet which is bridged over by a single steel truss noteworthy as being the longest in Switzerland. The engineers were obliged to resort to some very original measures on account of the local difficulties. The great steepness of the slopes of the valley allowed but little space for handling the material. There is no space on the upper ground at the left-hand end, since the mouth of the Stuckenegg tunnel is quite close to the steep bank. It was decided to use a system of cableways for handling the greater part of the material.

The main stone arches have 187 feet span, and several stone columns of unusual size enter into their construction. The highest of the piers is about 40 feet square at the base and runs up to 262 feet height. The viaduct has four such arches of 82 feet span, then comes the steel span, and on the other side there are two arches of 82 feet span and five small arches of 40 feet.

To build the steel truss high above ground a timber scaffolding of original shape was used. The base takes up but a small space. It was designed to stand the weight of the bridge truss, as well as the strong wind pressure. It sustained no damage despite storms and floods. An interesting operation was the construction of the truss span on the scaffolding. An electric elevator first installed on the lower platform and running to the top took up the iron parts for building a 12-ton cable hoist at the top level. When the hoist was in place it could be used to draw up the iron work which was needed in building the main bridge span. Meanwhile an air compressor plant had been installed for operating the pneumatic riveters for the bridge. In this way was built the middle part of the bridge truss to a length of 120 feet. Then came the task of building the rest of the length so as to reach the stone pillars on each side and cover the whole opening. In this case a good part of the truss overhangs the tower on both sides. The work was easily carried out by using a heavy traveling crane which runs on a track along the top level, as will be observed in one of our photographs. The crane had to be built on the top of the tower by material which was hoisted up from below. It could then be used in handling all the heavy iron parts in order to build the overhanging portions of the bridge on both sides of the tower so that at last the ends of the truss could be placed upon the stone piers which were to support them.

The Sitter viaduct—view looking toward the tunnel.

A GREAT SWISS ENGINEERING WORK

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

Our Backwardness in Invention

WE recently reprinted from *Engineering News* some comments on the encouragement of invention in Europe and the discouragement of invention by the large corporations of this country. As the result of a rather lively letter written by Mr William Kent, of Montclair, N J., to the *Engineering News*, the editor of that paper takes up the subject again In reply to the *Engineering News* statement that "We are to-day something like five years behind Germany in iron and steel metallurgy," Mr Kent gives a list of improvements which have been made in blast furnaces, steel works, hoisting and conveying apparatus, foundry machinery, gas-producers, rolling mills, and machine tools

The *Engineering News* recurs again to our backwardness in adopting the Diesel engine. "Notwithstanding the fact that the basic patents have expired so that any concern may build it, only a single firm in the United States to-day is selling Diesel engines" says the *Engineering News*, "and even this concern is not yet on a basis to push them on the market in competition with other machines.

In oil engines, the principal business in the United States has been done by a German concern manufacturing an engine invented in England In the development of gas-producers and suction gas engines most of the work done in this country has followed after the pioneer work done on the other side, and, notwithstanding the great stimulus to the use of the gas engine afforded by our stores of cheap natural gas, the internal combustion engine for power purposes is far more largely used abroad than here"

On the subject of the steel and iron industry, and the advance made by Germans, the *Engineering News* has this to state "It is perfectly well known that the blast furnace gas engine was fully developed and in successful commercial use in Europe about five years before it was taken up here" Our contemporary goes on to say that eleven years ago blast furnace gas engines were in use in Europe, which was about four years before the first blast furnace gas engines were installed at the Buffalo works of the Lackawanna Steel Company, cited by Mr Kent as an example of American up-to-dateness

In the electrical manufacture of steel, *Engineering News* points out that European inventors did the pioneer work, and that electric smelting furnaces were in extensive commercial use in Germany before American inventors thought it worth their while to take up this new invention

"The pioneer American steam turbine inventor, Dow, lacked the commercial knowledge to make his invention a commercial success, nor was he able to secure capital to develop it So the honors for pioneer work go to De Laval, the Swedish engineer, and to Parsons, the Englishman, while Curtis, another Englishman, and Rateau, a Frenchman, and Zoelly, a Swiss, and Riedler and Stumpf, in Germany, are the engineers who have won distinction in the later development of the steam turbine

"As for the multi-stage centrifugal pumps and blowers, these were in extended and successful use abroad years before they were taken up in the United States France developed the automobile far ahead of either England or America Telferage was originally invented by an English professor of engineering

"As for pioneer inventions in the railway field, the most important developments of the past five years in this country in locomotive design have been the Mallet locomotive (invented by the French engineer, Antoine Mallet, in 1888), and the use of superheated steam, for which credit must be given to the German, Schmidt"

In the opinion of our contemporary "The United States no longer leads the world in the race for invention, but it is better to know the truth than to delude ourselves with false pretensions to supremacy

"And now, as to the reasons why this country no longer leads It is not because American engineers and inventors are less ingenious or less progressive than those of other countries, though it may well be that the thorough work done by the German technical schools gives them some advantage in the development of inventions requiring a high degree of scientific knowledge

"We said in our former issue, and we now repeat, that the main reason, in our opinion, is that under the present organization of American manufacturing industry, invention and innovation is discouraged rather than encouraged And this opinion is based, not alone on knowledge of the actual experience of numerous American inventors and engineers, but on the frank statement of officers connected with some of our large industrial corporations

"We could cite the case of an American inventor who, after vainly endeavoring to secure capital for his work in his native country, went to England and won fortune, fame and honor. Another particularly pertinent example is the Gray beam mill, cited by our correspondent above as an example of American supremacy in pioneer inventions.

"The facts are that the inventor of the Gray mill for rolling wide-flange I-beams, after developing his invention and actually demonstrating its merits, was unable to market his invention with our excellent steel magnates They were not *obliged* to have his invention. They were making money by the cartload in consolidation and promotion and stock market manipulation. Why should they bother with such a trifle as an improved system of rolling beams?

"Mr Gray therefore went abroad, and the Belgium steel plant at Differdingen promptly took up his invention and developed a large and profitable business thereby Returning to America after this success abroad, Mr Gray was even then unable to secure a favorable hearing from the steel mill managers, whom Mr. Kent praises so highly It was not till the Belgian plant had been rolling Gray beams for five years that Mr. Schwab took it up at Bethlehem This former Steel Corporation president, engaging in a strenuous campaign of competition, may, perhaps, for this reason, have been more receptive to new ideas At any rate, the success of the 'Bethlehem beams,' and the tardy imitation of these shapes by other American steel mills, justifies his venture and proved the ultra-conservatism of those managers who, years before, rejected the Gray rolling process.

"We are well aware that the huge industrial combination has some advantages in undertaking the development of new inventions over the small concern. We are aware that some of our trusts do maintain research departments and it is currently said that one important use of these departments is to defeat the independent inventor and discourage the undertaking of original invention in the field which the trust aims to control. We are well aware, too, that there are numerous lines of labor-saving machinery which have been developed in the United States, but not abroad, because of the great difference in wage scales here and there All this has nothing to do with our contention that the United States has lost its supremacy as a field for the development of pioneer inventions, and that in the race of international competition we are failing behind because of the attitude of the trusts toward inventive progress."

A New Material for Safes Which Resists the Oxy-acetylene Blow-pipe

SAFE makers and safe breakers are engaged in a contest similar to that of the makers of guns and armor plate Safe breakers' methods have lately been much improved, especially by use of the so-called autogenous welding process which makes it possible to penetrate iron and steel plates of great thickness in a short time by means of the oxy-acetylene flame. This advance in criminal practice has produced corresponding improvements in the construction of safes and vaults. Lately the well-known armor plate makers, the Krupps of Essen, have produced a new material which is especially suitable for the protection of safes and vaults, as, according to a note in the journal *Autogene Metallbearbeitung*, it cannot be fused or penetrated by the oxy-hydrogen, or oxy-acetylene burners now in use, or at least it offers so great a resistance to fusion that an inordinately long time and enormous quantities of gas are required. The material is a variety of cast steel which is extremely hard and resists the best boring tools, so that it affords security also against mechanical forcing In order to make a hole 80 millimeters (3.2 inches) in a plate of this material, 40 millimeters (1.6 inches) thick, with the oxy-acetylene burner, from 6 to 14 hours' time, from 2,750 to 4,550 gallons of oxygen and from 2,500 to 3,700 gallons of acetylene are required, according to the results of a number of experiments The average safe breaker has not so much time or so much gas at his disposal. One of the steel cylinders in which compressed gases are transported contains about 1,460 gallons of (uncompressed) gas and weighs about 150 pounds. According to the most favorable results given above, at least four such cylinders would be required and their transportation, in addition to that of the other apparatus needed, is a task to stagger the boldest safe cracker. The extraordinary hardness of the plates opposes no serious obstacle to working them in the shop, as the rivet holes required can be made directly in the casting or they can be bored in softer steel parts especially provided for that purpose. The only defect of the plates is the present impossibility of making them thinner than 1.6 inches. It appears not improbable that this difficulty will be overcome, for only a year ago it was impossible to make the plates of less thickness than 8 inches, in which condition, of course, they were practically useless for the construction of safes and treasure vaults.

Heredity in Potatoes

IN the first number of *The Journal of Genetics*, a new journal devoted to problems in heredity, Dr. R. N. Salaman gives some results of a prolonged study on the inheritance of certain characters in the common potato (*Solanum tuberosum*).

Mendelian behavior was found in the sterility of the pollen in certain varieties, the sterility being dominant. Most of the experiments related, however, to the tuber. In regard to length, the tuber behaves, in inheritance, like the stem of the pea plant. The long type is dominant over the short. That is, where two varieties were crossed, one having short round tubers and the other long tubers, all the potatoes of the next generation were of the long type. But on breeding these hybrids by self-fertilization, the following generation gave three plants with long tubers to one plant with short tuber, in the typical Mendelian fashion The long tuber has more "eyes," which the author considers equivalent to nodes.

In some potatoes the eyes lie rather deep in the tuber, while in others they are near the surface, or quite on the outside When these two characters are brought together in fertilization, the deep eye character is dominant over the other.

The color of the tuber depends upon the amount of the pigment "anthocyan" present in the cell-sap of the superficial cells of the tuber, and varies from red to deep violet On analysing the results of the experiments, it appears that there are three distinct factors that have to do with the color appearance of a potato These are (1) a factor for redness, (2) one the purple or violet, and (3) a color "developer." Without this third factor no color appears at all The other factors determine the character of the color. The purple appearance depends upon the presence of all three factors; this is dominant over the red, and this in turn is dominant over the white, or absence of pigment.

In the study of another species of potato (*Solanum etuberosum*) for comparison, Mr. Salaman found some curious results In this species whiteness of tuber was dominant over pigmentation, roundness was dominant over long form, and superficial eyes dominant over deep-set. In all three respects this species is just the opposite of our garden variety

Incidentally it was observed that the sterile individuals in every culture were much more resistant to the potato-rot (*Phytophthora infestans*) than the ones bearing fertile pollen. This is a mater of great practical importance, since it may be possible to establish a race quite immune to this disease. As the sterile individuals are dominant, this resistance would appear to be of a different type from the resistance of wheat to the wheat-rust (*Puccinia graminis*) which was found to be recessive in the Cambridge experiments. It is a simpler matter to establish a race bearing recessive characters, but it may be possible to find a combination of characters in a potato that will include immunity to the rot.

The Cost of Substituting Steel for Wooden Cars

ACCORDING to an estimate in the *Railway Age Gazette*, the cost of substituting steel cars for the present wooden cars is estimated at about $400,000,000. At the beginning of this year there were about 2,000 passenger cars in service in this country, built of all steel construction. The total number of passenger coaches is about 54,000 so that the number of steel cars is about 3.3 per cent of the total. Of the cars constructed during the present year, 62 per cent will be all-steel construction, so that at the end of this year fully 9.3 per cent of all passenger cars will be of steel, while 3.5 per cent have steel underframes. The percentage of wooden cars in service has dropped in the last three years from 99.1 to 90.2 per cent.

Free Ships vs. Discriminatory Duties

To the Editor of the SCIENTIFIC AMERICAN:

The statement that the United States pays from $200,000,000 to $300,000,000 to foreign steamship lines for carrying passengers, freight, and mails is correct, with the sum nearer the $300,000,000 mark.

It is an economic fact also that under present conditions it is cheaper to pay foreign steamship lines for performing these services than to attempt it with American-built tonnage aided by subsidies or discriminatory duties.

Such a state of affairs is, in the long run, detrimental to all American interests. In the case of two European nations, if not three, their mercantile fleets are practically dependent on American traffic for existence. Our present system keeps alive our sea rivals and hinders the development of our export trade.

That the United States should be restored to their old position in the deep-sea trade, is imperative from a political as well as from an economic standpoint. Without an adequate merchant marine as an auxiliary to our navy, our battleship fleet is like a hull without an engine—only half equipped for its work.

We have a big navy, and it is growing larger all the time, yet it is as dependent to-day on foreign built and owned steamers for transports, colliers, etc., as it was when the Spanish war broke out. The United States paid some $20,000,000 or more then for the obsolete tonnage that foreigners dumped on Uncle Sam.

The views of Mr. Bowles, formerly an admiral of the United States navy, now president of the Fore River Ship Building Company, are entitled to great respect.

His company is building the two battleships for the Argentine navy, and it has turned out some high-class coast freighters. His statement, therefore, "the experience of sixty years of 'free trade' in ocean transportation conclusively shows that it is not profitable to American capital under present conditions, and requires protection or some form of government aid or subsidy," merits marked consideration.

Mr. Bowles seeks to overcome conditions of "free trade" which exists in the deep-sea trade by the application of "protective principles:"

"First, by mail compensation such as is provided for under the ocean mail act of 1891 and which is still in effect.

"Second, the remission of the head tax of $4 when immigrants arrive in the United States in American registered steamers.

"Third, by discriminatory duties applicable to American-built steamers of all types. . . A reduction of 5 per cent on all goods on which the ad valorem duties exceed 41 per cent, and on all goods under 41 per cent or free the importer shall receive an importer's certificate available only for the payment of duties at the custom house and equal in value to 2.05 per cent of the value of the goods so imported."

The mail compensation act is still in effect, but it has done little good so far; it could be made of value in establishing new lines if American capital were generally employed in ocean shipping under the American flag.

The second proposition, the remission of the head tax of $4 when immigrants arrive in American steamers. It should be amended by establishing a stamp tax of $4 on all outward emigrant tickets, the same to be remitted in case the passenger sails on an American steamer.

Foreign governments do not hesitate to legislate to make the emigrant traffic a source of profit to the State and to the upbuilding of their merchant marine.

Third: The discriminatory duty." This is highly objectionable. The refund to the steamer or the importer would run from $2.25 per ton on sugar to $4.50 on a ton of coffee.

These articles, as well as hides, flax, fruits, fibers, are imported in cargo lots. An American steamer operated under such discriminatory duties would earn approximately 50 to 100 per cent more than a foreign steamer in the same trade. Under such conditions the American steamer would control the traffic in such commodities, and the control of the import would carry with it the control of the export, and subject exporters to such rates of freight as the traffic would bear.

It would almost to a certainty create a monopoly in the deep-sea trade as effective as now exists in the coastwise.

Although the United States have never tried the policy of "free ships" for upbuilding our merchant marine, the advocates of subsidy and discriminatory duties have always denounced it as a fallacy, yet those nations which have adopted it, are the most progressive and successful ship-owning nations.

For over one hundred years our shipbuilders have been shielded from the competition of foreign builders; this has resulted in developing our coastwise and lake shipping, but it has steadily lost us the deep-sea foreign trade till it is now practically extinct. In justification of this, it is stated that it costs from 40 to 50 per cent more to build steamers of the same size in American yards than in foreign. This would seem to indicate that the American prices are excessive.

It is also true that shipbuilding material may be imported free if used in building American steamers engaged in foreign trade. This privilege, however, is so hedged about with restrictions as to be practically valueless.

"Shipbuilder's (American) labor costs are 70 to 100 per cent more than the foreigner."

This is also equally true of labor engaged in making everything, from needles to automobiles, ship plates, and rails. Yet we are constantly exporting a greater quantity of all kinds of these and other manufactured goods every year. And if the American scale of wages can be paid on American goods sold in foreign markets in competition with goods of foreign manufacture, it would not be unreasonable to expect that our ship builders could compete with the foreign builder on steamers built for foreign trade only.

In the case of the two battleships being built for the Argentine government, it was done. The contract was secured in competition with foreign competitors, and it is to taken for granted that the labor employed in building these ships receives the American wage scale.

It is stated that to build the hulls of the battleships costs more in the American yards, but that Americans can turn out big guns and armor plates so much cheaper than can the foreigner, that the total cost of building in American yards is less than the foreigner's price.

It is something to be proud of—to be able to build armor and big guns cheaper than can European concerns; and as this is the case, it is somewhat difficult to see why steamers cannot likewise be built cheaper in American yards. The labor in gun and armor making is as well paid as labor employed in shipbuilding. A few years ago Krupp offered armor plate to the United States at much under the American prices. Now apparently American makers can undersell Krupp.

Justification for denying American registration to foreign-built, American-owned tonnage is that it costs more to operate the foreign-built under the American flag and that Americans would not avail themselves of the privilege.

Congress has been petitioned to pass such a bill, and assurances were given that on its passage a fleet of modern fast boats would be enrolled under the American flag for foreign trade. Yet Congress hesitates to pass such a measure, although no American interest could be injured in any way.

Another stated objection to the admission of "free ships" is that "the admission of foreign-built steamers would kill the art of shipbuilding in the United States." Well, as far as building for the foreign trade is concerned, it is dead now. It is some years since any steamers were built for trans-Atlantic trade, and the few built in the last decade were in many cases put under foreign flags and are now operated between European and American ports.

Holland, Norway, Sweden, Belgium, are countries with a small population and but little natural resources, yet owing to their free ship policy they have fleets of merchant steamers that trade in every quarter of the globe.

Up to 1849 England had navigation laws similar to those of the United States. In that year they were repealed, and with their passing England's shipping began to expand till to-day she is far and away the most important shipping nation in the world.

Germany took pattern by England and also passed a free-ship measure which is still in effect and her merchant marine began to expand, she has continued the policy of allowing German citizens to buy or build steamers in the cheapest market, granting German registration, to this day. In addition, all shipbuilding material is admitted free of duty into Germany.

This policy has placed her second among the shipping nations of the world, and it has aided the development of her shipyards, they have kept pace with the growth of the German tonnage and to-day vie with England in turning out the largest and fastest steamers afloat.

France is the one European country that stands out pre-eminently as a believer in bounties for shipbuilders and subsidies for tonnage. Her policy has been in effect for years, she pays enormous sums annually in aid of her merchant marine, yet it is a negligible factor as compared with England and Germany, and hardly compares with many of the smaller countries.

The freight rates on French ships are higher than on tonnage of countries not subsidized, and tonnage of other countries has no difficulty in competing with the French, even to the ports of France.

The policy of subsidy and bounty followed by France may induce the building of steamers, but it does nothing to advance trade and commerce.

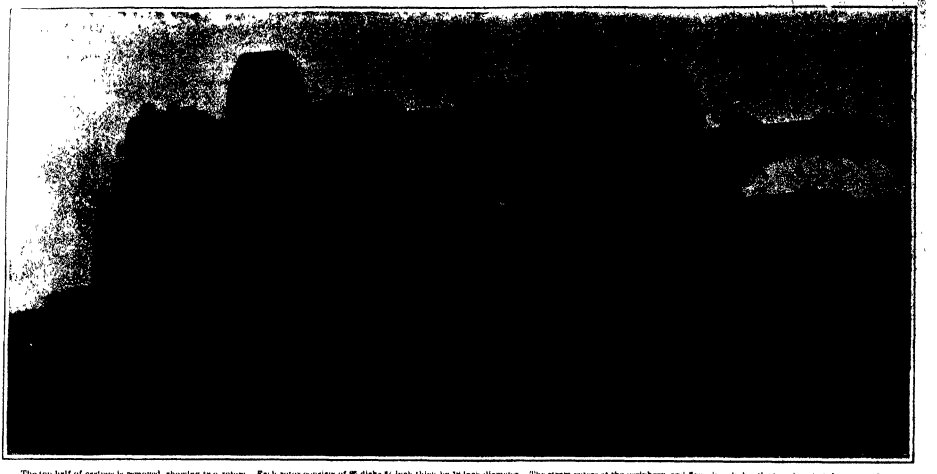
For our foreign trade we need a merchant marine, and to secure it we should have "free ships." It is pointed out by Admiral Bowles that to move one-third of our present foreign commerce, it would require ten years to build the necessary steamers—and the Panama canal is to be opened in 1915, possibly in 1913 according to Col. Goethals. At the outside, less than four years from now steamers will be using this canal.

A free-ship bill is the solution of the American merchant marine. It can do no harm to any American interest. Our yards build no tonnage for the foreign trade, even if they could compete to-day, they could do no more than keep pace with the ever increasing demand for tonnage.

If it is necessary to subsidize to keep our shipyards going let it be for steamers of the highest class and of high speed—20 knots at least, steamers that will be of value in case of war, and that can deliver mails and passengers to South American ports in quicker time than is now possible. Such steamers will do something to stimulate travel and intercourse between the nations of South America and the United States.

The great lines of traffic are operated by steamers of moderate speed and low cost of operation, and until we can build steamers of such a type as cheaply as foreign builders, Americans should be allowed to buy foreign built steamers with the privilege of American registration to ply in foreign trade only. With the passage of such a bill, tonnage under the American flag would rapidly increase and our commerce correspondingly expand, and not the least important benefit to follow, will be that our battle fleet will have an ample supply of colliers and transports.

Chicago, Ill. CHARLES DUPEYET



Oil as a Locomotive Fuel

THE advent of fuel oil has become an important factor in railway locomotion. It is estimated by the United States Geological Survey that from 20,000,000 to 23,000,000 tons of coal per annum are replaced by oil, and a large part of this is used by locomotives.

In this connection there is interest in a statement which will appear in the forthcoming petroleum report of the Geological Survey showing the extent to which oil is used as a locomotive fuel. The author of this report, David T. Day, computes the total length of railway lines operated during 1910 with petroleum as a fuel to be 30,776 miles, a mileage practically equivalent to that of two complete transcontinental lines stretching across the United States from ocean to ocean. The number of barrels of fuel oil used by the railroads (42 gallons per barrel) was 24,526,683. This includes 766,765 barrels used by the railroads as fuel other than in locomotives. The total number of miles run by oil burning engines during the year was 88,318,947. This would have carried one engine or train around the world approximately 3,530 times.

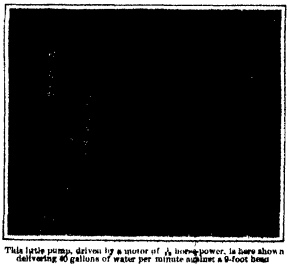
The advantages of oil as locomotive fuel over coal have been stated by Eugene McAuliffe as many. They include decreased cost of handling oil from cars to engines, with practically no loss by depreciation due to such handling; evaporation losses suffered by coal as not applying to oil; saving of time at terminals for engine cleaning and providing increased mileage per engine, the oil capacity of the tender being about 150 per cent of that of coal, freedom from physical failure of firemen in extreme hot weather, delivery of oil being unaffected by labor conditions, the coal situation necessitating in some instances heavy storage at great expense, greater cleanliness in handling all passenger trains, lack of smoke and immunity from right-of-way forest fires.

The expense of equipping the average locomotive to burn oil is about $800, and the cost of large steel storage tanks is about 25 cents per barrel but the necessary terminal facilities for handling oil cost 50 per cent less than the amount required to handle coal.

The top half of casings is removed, showing two rotors. Each rotor consists of 25 disks ⅛ inch thick by 18 inch diameter. The steam enters at the periphery, and flows in spiral paths to exhaust at the center of the disks. The driving turbine is to the left, the brake turbine to the right. Between them is a torsion spring. The steam inlets are on opposite sides on the two rotors; the driving rotor moving clockwise. The torsion of the spring is automatically shown by beams of light and mirrors and the horse-power is read off a scale. At 9,050 revolutions per minute, with 185 pounds at the throttle and free exhaust, this turbine develops 200 horse-power. It weighs two pounds per horse-power.

The Tesla turbine testing plant at the Edison Waterside Station, New York.

The Tesla Steam Turbine



The Rotary Heat Motor Reduced to Its Simplest Terms

IT will interest the readers of the SCIENTIFIC AMERICAN to know that Nikola Tesla, whose reputation must, naturally, stand upon the contributions he made to electrical engineering when the art was yet in its comparative infancy, is by training and choice a mechanical engineer, with a strong leaning to that branch of it which is covered by the term "steam engineering." For several years past he has devoted much of his attention to improvements in thermo-dynamic conversion, and the result of his theories and practical experiments is to be found in an entirely new form of prime movers shown in operation at the Waterside station of the New York Edison Company, who kindly placed the facilities of their great plant at his disposal for carrying on experimental work.

By the courtesy of the inventor, we are enabled to publish the accompanying views, representing the testing plant at the Waterside station, which are the first photographs of this interesting motor that have yet been made public.

The basic principle which determined Tesla's investigations was the well-known fact that when a fluid (steam, gas or water) is used as a vehicle of energy, the highest possible economy can be obtained only when the changes in velocity and direction of the movement of the fluid are made as gradual and easy as possible. In the present forms of turbines in which the energy is transmitted by pressure, reaction or impact, as in the De Laval, Parsons, and Curtiss types, more or less sudden changes both of speed and direction are involved, with consequent shocks, vibration and destructive eddies. Furthermore, the introduction of pistons, blades, buckets, and intercepting devices of this general class, into the path of the fluid involves much delicate and difficult mechanical construction which adds greatly to the cost both of production and maintenance.

The desiderata in an ideal turbine group themselves under the heads of the theoretical and the mechanical. The theoretically perfect turbine would be one in which the fluid was so controlled from the inlet to the exhaust that its energy was delivered to the driving shaft with the least possible losses due to the mechanical means employed. The mechanically perfect turbine would be one which combined simplicity and cheapness of construction, durability, ease and rapidity of repairs, and a small ratio of weight and space occupied to the power delivered on the shaft. Mr. Tesla maintains that in the turbine which forms the subject of this article, he has carried the steam and gas motor a long step forward toward the maximum attainable efficiency, both theoretical and mechanical. That these claims are well founded is shown by the fact that in the plant at the Edison station, he is securing an output of 200 horse-power from a single-stage steam turbine with atmospheric exhaust, weighing less than 2 pounds per horse-power, which is contained within a space measuring 2 feet by 3 feet, by 2 feet in height, and which accomplishes these results with a thermal fall of only 130 B T U, that is, about one-third of the total drop available. Furthermore, considered from the mechanical standpoint, the turbine is astonishingly simple and economical in construction, and by the very nature of its construction, should prove to possess such a durability and freedom from wear and breakdown as to place it, in these respects, far in advance of any type of steam or gas motor of the present day.

This little pump, driven by a motor of ¼ horse-power, is here shown delivering 40 gallons of water per minute against a 9-foot head.

The turbine used as a pump.

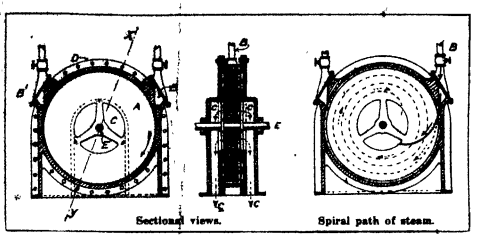
This view shows one-sixteenth inch pressure pipe, with the steam throttle shown, and below it the reversing valve and the compact turbine. Note the many speed nuts in the tests.

A 200-horse-power high-pressure turbine.

Briefly stated, Tesla's steam motor consists of a set of flat steel disks mounted on a shaft and rotating within a casing, the steam entering with high velocity at the periphery of the disks, flowing between them in free spiral paths, and finally escaping through exhaust ports at their center. Instead of developing the energy of the steam by pressure, reaction, or impact, on a series of blades or vanes, Tesla depends upon the fluid properties of adhesion and viscosity—the attraction of the steam to the faces of the disks and the resistance of its particles to molecular separation combining in transmitting the velocity energy of the motive fluid to the plates and the shaft.

By reference to the accompanying photographs and line drawings, it will be seen that the turbine has a rotor *A* which in the present case consists of 25 flat steel disks, one thirty-second of an inch in thickness, of hardened and carefully tempered steel. The rotor as assembled is 3¼ inches wide on the face, by 18 inches in diameter, and when the turbine is running at its maximum working velocity, the material is never under a tensile stress exceeding 50,000 pounds per square inch. The rotor is mounted in a casing *D*, which is provided with two inlet nozzles, *S* for use in running direct and *S'* for reversing. Openings *C* are cut out at the central portion of the disks and these communicate directly with exhaust ports formed in the side of the casing.

In operation, the steam, or gas, as the case may be, is directed on the periphery of the disks through the nozzle *S'* (which may be diverging, straight or converging), where more or less of its expansive energy is converted into velocity energy. When the machine is at rest, the radial and tangential forces due to the pressure and velocity of the steam cause it to travel in a rather short curved path toward the central exhaust opening, as indicated by the full black line in the accompanying diagram; but as the disks commence to rotate and their speed increases, the steam travels in spiral paths the length of which increases until, at



In the case of the present turbine, the particles of the fluid complete a number of turns around the shaft before reaching the exhaust, covering in the meantime a lineal path some 12 to 16 feet in length. During its progress from inlet to exhaust, the velocity and pressure of the steam are reduced until it leaves the exhaust at 1 or 2 pounds gage pressure.

The resistance to the passage of the steam or gas between adjoining plates is approximately proportional to the square of the relative speed, which is at a maximum toward the center of the disks and is equal to the tangential velocity of the steam. Hence the resistance to radial escape is very great, being furthermore enhanced by the centrifugal forces acting obliquely. One of the most destructive enemies in a perfected turbine is that of irreversibility, and we are not familiar with the many and frequently cumbersome means which have been employed to secure this end, but with the knowledge that this turbine is admirably adapted for reversing, since this effect can be secured by merely closing the right-hand valve and opening that on the left.

It is evident that the principles of this turbine are equally applicable, by slight modifications of design, for its use as a pump, and we present a photograph of a demonstration model which is in operation in Mr. Tesla's office. This little pump, driven by an electric motor of 1/12 horse-power, delivers 40 gallons per minute against a head of 9 feet. The discharge pipe leads up to a horizontal tube provided with a wire mesh for screening the water and checking the eddies. The water falls through a slot in the bottom of this tube and after passing below a baffle plate flows in a steady stream about ⅝ inch thick by 18 inches in width, to a trough from which it returns to the pump. Pumps of this character show an efficiency favorably comparing with that of centrifugal pumps and they have the advantage that great heads are obtainable economically in a single stage. The runner is mounted in a two-part volute casing and except for the fact that the place of the buckets, vanes, etc., of the ordinary centrifugal pump is taken by a set of disks, the construction is generally similar to that of pumps of the standard kind.

In conclusion, it should be noted that although the experimental plant at the Waterside station develops 200 horse-power with 125 pounds at the supply pipe and free exhaust, it could show an output of 300 horse-power with the full pressure of the Edison supply circuit. Furthermore, Mr. Tesla states that if it were compounded and the exhaust were led to a low pressure unit, carrying about three times the number of disks contained in the high pressure element, with connection to a condenser affording 28½ to 29 inches of vacuum, the results obtained in the present high-pressure machine indicate that the compound unit would give an output of 600 horse-power, without great increase of dimensions. This estimate is conservative.

The testing plant consists of two identical turbines connected by a carefully calibrated torsion spring, the machine to the left being the driving element, the other the brake. In the brake element, the steam is delivered to the blades in a direction opposite to that of the rotation of the disks. Fastened to the shaft of the brake turbine is a hollow pulley provided with two diametrically opposite narrow slots, and an incandescent lamp placed inside close to the rim. As the pulley rotates, two flashes of light pass out of the same, and by means of reflecting mirrors and lenses, they are carried around the plant and fall upon two rotating glass mirrors placed back to back on the shaft of the driving turbine so that the center line of the silver coatings coincides with the axis of the shaft. The mirrors are so set that when there is no torsion on the spring, the light beams produce a luminous spot stationary at the zero of the scale. But as soon as load is put on, the brake is deflected through an angle which indicates directly the torsion. The scale and spring are so proportioned and adjusted that the horse-power can be read directly from the deflections noted. The indications of this device are very accurate and have shown that when the turbine is running at 9,000 revolutions under an inlet pressure of 125 pounds to the square inch, and with free exhaust, 200 brake horse-power are developed. The consumption under these conditions of maximum output is 38 pounds of saturated steam per horse-power per hour—a very high efficiency when we consider that the heat-drop, measured by thermometers, is only 130 B T U, and that the energy transformation is effected in one stage. Since about three times this number of heat units are available in a modern plant with superheat and high vacuum, the above means a consumption of less than 12 pounds per horse-power hour in such turbines adapted to take up the full drop. Under certain conditions, however, very high thermal efficiencies have been obtained which demonstrate that in large machines based on this principle, in which a very small slip can be secured, the steam consumption will be much lower and should, Mr. Tesla states, approximate the theoretical minimum, thus resulting in nearly frictionless turbine transmitting almost the entire expansive energy of the steam to the shaft.

Details of turbine.

Some Striking Coal Facts

LAST year the United States mined 501,596,378 short tons of coal or nearly two-fifths of the year's total production for the world. This coal would load a train stretching back and forth across the United States from the Atlantic to the Pacific 33 times—a train approximately 100,000 miles long. Eleven years ago the United States for the first time surpassed Great Britain with a production of 253,741,192 tons, only a little more than half of last year's output. The mere increase of the coal output of the United States for 1910 over that of 1909—40,781,762 tons—was greater than the total production of any foreign country except Great Britain, Germany, Austria, Hungary, or France.

This turbine, whose rotor contains simply a set of flat disks 18 inches in diameter, develops 200 brake horse-power on test.

Turbine with upper half of casing removed.

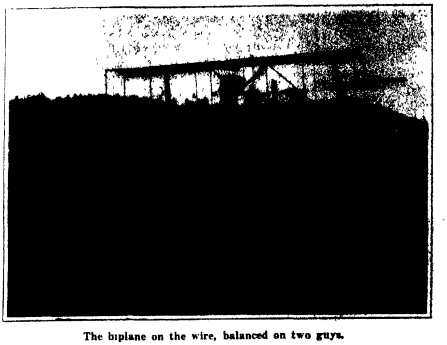
This increase alone was one and one-fifth times as great as the entire production of the United States in 1870, surpassing only Great Britain and Germany, either of the states of Pennsylvania or West Virginia produced in 1910 more coal than any foreign country. For the past seven or eight 10-year periods the coal production for each decade has been about equal to the entire amount of coal previously mined in the United States. Thus in the 10 years between 1885 and 1895 the production was 1,585,098,841 tons, while the entire amount of coal mined prior to 1895 was only 1,559,080,473 tons. In the 10 years between 1895 and 1905 the production was 2,822,462,746 tons, while all the coal which had been mined prior to 1895 was 3,138,174,119 tons.

Incredible as it may seem, at the present rate of increase the ten year period between 1905 and 1915 will show a production greater than all the coal mined in the United States prior to 1905. In 1850 the per capita production of coal was a little over one-fourth of a ton. In 1870 the per capita production had increased to nearly one ton, in 1890 it was 2½ tons, in 1900 it was 3½ tons, and in 1910 with the population of 91,972,266 the production was nearly 5½ tons for each person.

Last year 725,030 men mined coal in the United States. The great coal production record of 1910 was made in spite of a series of labor strikes participated in by 215,640 men. The loss in wages alone amounted to nearly $20,000,000.

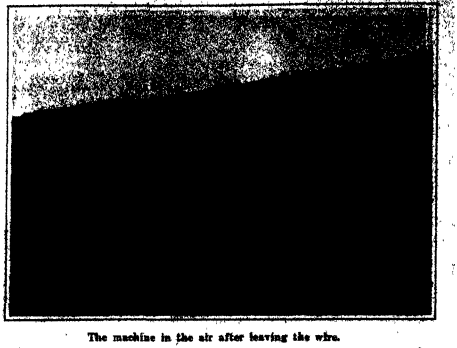
The quantity of coal used for making coke in the United States for metallurgical purposes was 52,187,450 tons. This is additional to by-product coke produced in gas manufacture.

The total production of coal in the United States at the close of 1910 was 8,243,351,259 short tons. This plus the estimated loss incident to mining makes a total exhaustion of 13,395,000,000 tons. The United States Geological Survey estimates the original supply of coal in the ground in the United States, exclusive of Alaska, at 3,076,204,000,000 tons. This original supply less the exhaustion at the close of 1910 leaves an apparent supply still available of 3,062,808,972,000 tons, or 99.6 per cent of the original supply. In other words, in all the time since coal mining began in the United States the draft upon the original supply including loss in mining, has amounted to less than one half of one per cent. At the present rate of production of approximately half a billion tons a year the coal reserve of the United States would therefore last 6,000 years. At the present rate of increase in production, however, these three thousand billion tons of coal in the ground would last only a few generations.



Foreign Students in America

ADDRESSING the House of Representatives on the many new activities of the United States diplomatic service, Representative Foster, of Vermont, late chairman of the House Foreign Affairs Committee, recently called attention to the effort made by our diplomatic and consular representatives to advertise the United States as an educational center, an undertaking that has been fruitful of results.



One of the outcomes of this program was the formation in Buenos Aires two years ago of a United States University Club, which has been the means of sending at least 20 young Argentinians to this country to be educated. Under the auspices of this club lectures are given on university life in the United States, illustrated with a large number of appropriate stereopticon views. Negotiations are now under way for an interchange of schoolboys between the Boston High School of Commerce and the preparatory department of the University of La Plata. There are now at least 400 Latin Americans studying in the United States, and the number is steadily increasing.

Through the efforts of our ambassador at Constantinople supported by the State Department, Columbia University has voted to receive, free of all tuition charges, three students annually from the Ottoman Empire for the next ten years, to pursue courses of study in any of the departments of the university. These students are to be selected by the Ottoman government, with the advice and approval of the ambassador at Constantinople.

The education of Chinese students in America, a matter in which the United States government has always taken a kindly interest, is assuming ever larger proportions. These students now number between 800 and 900. Half of these are "government students" supported by the different Chinese provinces and by the remitted portion of the Boxer indemnity fund. To insure that the indemnity students coming to the United States should not start with a serious handicap, but be fully prepared to enter the American colleges, an academy has been established in Peking by the Chinese government where these students receive preliminary instructions under American teachers.

The biplane on the wire, balanced on two guys.

The machine in the air after leaving the wire.

Launching an Aeroplane from a Wire

The New Curtiss Naval Flying Machine

By far the most serious problem which confronts the Navy Department in its effort to utilize aeroplanes is the difficulty of providing a suitable launching and alighting gear. Every one knows nowadays that before it can really fly, an aeroplane must be in motion; that, like any soaring bird, it must make an initial run in order to get up speed. Alighting on land has always presented its difficulties. Indeed, it may be safely said that the landing chassis as we know it is capable of much improvement. How much more difficult must it be to land on water?

The first experiments which were made in our navy with the aeroplane involved the use of a rather extensive platform on the forecastle of the scout cruiser "Birmingham." Down this platform, at a fairly steep angle, Ely in a Curtiss biplane, ran on November 8th of last year, and for the first time in history succeeded in launching a flying machine from the deck of a warship. Two months later he succeeded in starting from and alighting upon the "Pennsylvania."

Remarkable as this achievement was, it is obvious that warships cannot carry about with them platforms of such size. In action, every piece of unnecessary apparatus, every incumbrance, is simply tossed overboard. The platform unquestionably would have to go with the rest, if the ship is to be fought at all.

Mr. Glenn H. Curtiss seems to have succeeded in overcoming these difficulties, by adopting the hydroplane construction. He has shown that it is possible both to start from the water and to alight upon it with comparative ease and safety. In a word, he devised a type of flying machine peculiarly adapted to the needs of the navy.

The problem of providing a suitable launching gear, which can be used when the water is too rough for the hydroplane float, seems now to have been solved with equal felicity. At Hammondsport, on Lake Keuka, Curtiss has been making experiments which show that it is possible to launch a hydro-aeroplane from a wire cable. Perhaps the most successful trials were made by Lieut. Ellison. According to Mr. Curtiss, it would only be necessary to stretch one wire from the boat deck of a battleship down to the bow. On this cable the hydroplane glides down, being kept from falling by two auxiliary wires which support the wings until the machine gets up sufficient headway to keep its own balance by means of the ailerons or other control.

Such a launching gear does not interfere in any way with the guns or armament and can be stowed away after it has served its purpose in a very short time.

The experiment shows that whenever the sea is too rough to permit the hydroplane to rise from the waves, it can always take the air by means of the cable.

Submarine Cables and Longitude Determination

The Improvements Devised by Colonel Bourgeois

By Jacques Boyer

An accurate comparison between two astronomical clocks, situated at a great distance from each other, can be made by overland telegraphy, by means of which the time signals given by both clocks are recorded, side by side, on an electric chronograph at each station. The ordinary electric chronograph is provided with two pens, or writing points, operated by electro-magnets, so that each pen makes a distinctive mark on the same uniformly rotating cylinder or moving strip of paper, when the circuit of its electro-magnet is made or broken. Usually one pen marks the time by the local clock, while the other records signals made by the observer, on the passage of a star over the wires of the transit instrument or the occurrence of any other event. For the determination of longitude, the electro-magnet of the second pen is connected with the clock at the distant station.

In order to determine the difference of longitude between two stations by this method, it is necessary to transmit from each station to the other currents

THE EMPLOYMENT OF SUBMARINE CABLES IN THE DETERMINATION OF LONGITUDE

Current Astronomical Events

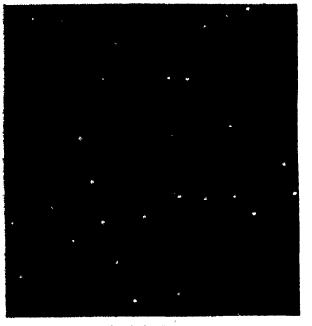
Brooks's Comet; The Harvest Moon

Brooks's Comet

How to Find It Without the Aid of a Telescope

By E. A. Mitchell, Professor of Astronomy at Columbia University

THERE is hardly a person anywhere who is not interested in a comet, and at the present time one is visible each night without the aid of a telescope. Moreover, it is not at the limit of visibility to the naked eye, but one which can be readily seen by anyone who cares to spare a few minutes watching for it.



The comet known to astronomers as Brooks's, or Comet 1911c, was discovered on the night of July 20th by the famous comet-seeker at Geneva, N. Y. When discovered, it appeared as a faint hairy star, without a tail, entirely unlike the popular idea of a comet. Observations on this and the following few nights gave astronomers the opportunity of calculating its path with respect to the sun, and in relation to the earth. These calculations furnish an ephemeris which gives the position in the sky where the comet may be found. Such a calculation is a laborious piece of work, which must be done with great precision, and with care that no mistakes are made in the additions and subtractions. Ordinarily when a comet is discovered a parabolic orbit is first computed, for this calculation is the easiest and presents the fewest difficulties. Such an orbit is quite an impossible thing in astronomy, but on account of the simplicity, it is adopted because it gives the position of the comet near enough for all practical purposes.

If the comet is an interesting one, or if it is the return of one formerly discovered, then the more difficult elliptical elements are calculated. In the case of Halley's comet, this was an exceptionally difficult undertaking, for the "perturbations" or attraction of the various planets led to serious complications.

Several sets of calculations have been made for Brooks's comet, one of the most reliable being that of F. E. Seagrave of Providence, R. I. The ephemeris for the end of September and beginning of October follows:

Date.	Right Ascension. h	m	s.	Declination. deg.	m.	s.
September 21st	15	31	15	+ 55	0	39
September 25th	14	51	17	49	21	7
September 29th	14	17	44	44	58	56
October 3rd	13	49	52	40	6	42
October 7th	13	26	46	34	51	0

The amateur with his small telescope and circles can readily find the comet from this table. Right ascension and declination in the sky correspond to longitude and latitude on the earth. A ship at sea is located by knowing its longitude and latitude, or New York city is found by knowing that its longitude is 74 degrees west, and its latitude 40 degrees 48 minutes north. The stars are kept track of by means of their right ascensions and declinations. As we can locate a certain direction from New York, so we can locate the comet from its position with respect to the stars without paying attention at all to the figures which give the right ascensions and declinations.

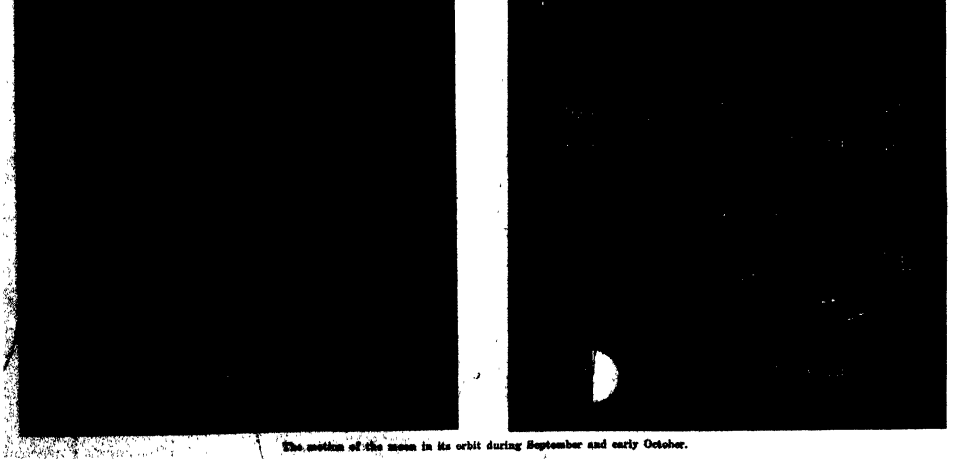
The path of the Brooks comet.

On September 2nd a photograph by Prof. Barnard exhibited a tail eight degrees in length, which corresponded in extent to 10,000,000 miles. At the same time the head measured 500,000 miles across. The comet was closest to the earth on September 17th, when it was readily visible as a fourth magnitude star. It was then forty-eight million miles away from us. Steadily the comet is speeding toward the sun, the great central luminary which exerts its attractive influence on all bodies of the solar system. On October 27th, the comet will be at perihelion, when it will be 45,000,000 miles distant from the sun, which is as close as it will approach that body. At the middle of September, the comet was a circumpolar object at 57 degrees north declination. Its motion has been southwest more than a degree each day.

On September 30th, the comet will be as bright as the fifth magnitude and can be quite easily found near the end of the handle of the "Big Dipper." The handle takes a crook in it at the well-known double star Mizar. Follow from Mizar to the end of the handle, and in a straight line five degrees farther on, the comet may be seen, or, in other words, the comet will be about half way between the end of the handle of the "Dipper" and the third magnitude star Gamma Bootis. The comet will set about 10 o'clock. One should look for it immediately after sunset (though the moon will interfere somewhat) before the comet gets too near the horizon. The comet's rapid motion makes it set earlier each night, so that on October 7th it sets at 9 P. M. It will soon set as early as the sun when it will become invisible to be seen later in the month before sunrise.

Though the head of the comet has been quite bright, its tail has been difficult to see in the telescope because it is so faint. It needed a long exposure to photograph the tail.

The world is still waiting for a brilliant comet to appear, one which may be seen in the sky in spite of the electric lights of the city and without special diagrams, one which will rival the great comet of 1882.



The Harvest Moon

By Frederic R. Honey, Professor of Astronomy at Trinity College

THE term "harvest moon," originating in England, where the brilliant moonlight of several consecutive evenings aided the harvesting of crops, is the popular expression for the moon at its full in the month of September in northern latitudes. This phenomenon of early moon-rise is dependent upon the degree of retardation of the moon's rising, as affected by difference in latitude. As conditions in England are especially favorable, full moon-rise at harvest time therefore occurs earlier than in the lower latitudes of this country. Following out this law of retardation, it is a matter of course to look for a yet earlier rising of the "harvest moon" in the far north of the Scandinavian peninsula; and an extremely opposite condition in the corresponding latitudes of the Southern hemisphere, where the "harvest moon" (if it were possible to use the term in this region) would occur about the time of the vernal instead of the autumnal equinox.

Variations in the retardation of the moon's rising (a retardation which averages about 51 minutes daily) are due to complex conditions. If the earth's axis were perpendicular to the plane of the ecliptic, and if the earth and moon revolved in circular orbits at uniform velocities around their respective centers of motion in that plane, the retardation would obviously be constant. But the earth's axis is inclined at an

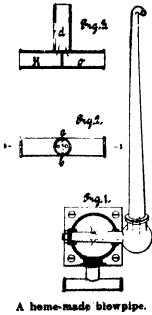
The motion of the moon in its orbit during September and early October.

The Laboratory



Some Suggestions for Home Experiment

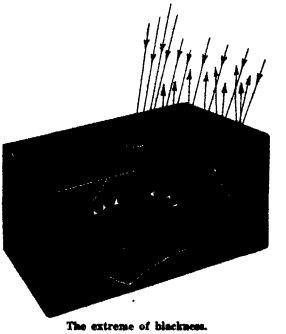
The Amateur's Oxy-hydrogen Blowpipe

By A. J. Jarman

So many interesting experiments may be performed with the oxy-hydrogen blowpipe that it is almost an essential of the amateur's laboratory. With it not only may any of the metals (platinum and iridium not excepted) be fused, but earthy bodies as well may be combined with various metallic oxides. The blowpipe illustrated herewith was designed by the writer, and used for many years. The construction is very simple. Procure a swivel joint, such as is illustrated in Fig. 1. If a joint of that exact type cannot readily be found, the amateur may devise one from the fittings of a gas light bracket. This joint should be firmly secured to a base of hard wood, such as mahogany. An ordinary brass blowpipe, of the type used in the mouth, should be secured to the swivel joint, as indicated at *a* in Fig. 1. The best way to do this is to cut off the lower end of the blowpipe with a triangular file, twist a piece of copper wire around the end, and press it into the joint, and then secure it by soldering it with soft solder. The joint should be air-tight. The other part of the swivel joint should be fitted with a device such as illustrated in Figs. 2 and 3. It consists of a piece of brass or copper pipe, of ⅝-inch outside diameter. With a hack-saw make a cut in the pipe at the middle, as indicated at *b, c*, Fig. 2. Insert a small strip of brass or tin plate in this cut and solder it firmly in place, making sure that the joint is air-tight all around, so that the pipe is divided into two separate compartments. Drill two small holes in the tube, one at each side of the tin partition. Then solder a nipple *d* to the brass tube, so that it fits over the holes just referred to. In every case the soldering should be so done as to prevent leakage of gas or air at the joints. The nipple *d* should be screwed into the swivel joint, as indicated in Fig. 1. The two sections of the pipe may be connected by rubber tubing to the oxygen and hydrogen sources of supply. In order that the rubber tubing may be firmly held to the brass pipe, it is best to solder a ring of brass wire to the edge, forming a flange.

The hydrogen (carbureted) may be obtained from a gas bracket after removing the tip or burner. The other side of the tube, marked *o* in Fig. 3, should be connected to the oxygen supply, which may either be a cylinder of compressed oxygen, a gas holder, or a gas bag. In use, first turn on the hydrogen or the coal gas and light it at the nozzle of the blowpipe. Then gradually turn on the oxygen. The two gases will commingle in the nipple *d*, and in the swivel joint, and the presence of the oxygen in the gas will immediately be attended by a reduction of the length of the flame. Turn on the oxygen slowly until a very brilliant bluish green flame protrudes from the blowpipe nozzle. This will indicate the hottest flame obtainable from the mixture. In case of an excess of oxygen, the mixture will ignite within the blowpipe, producing an explosion, which, however, will not be of serious proportions. A piece of battery carbon forms a very good fusion plate upon which the material to be treated may be placed. Slate dust, graphite, glass powder, and many of the metallic oxides, may be fused with this blowpipe. A small quantity of powdered borax aids the fusion of the oxides. Metals of any kind may be welded together, even platinum. The blowpipe may be used to produce a brilliant lime-light by letting the flame impinge upon a stick of common lime, mounted on the end of an iron wire rod, and shaped with a file with a hole at the center of the cut drilled with a brad awl. A light of from 200 to 400 candle-power can thus be produced, with which excellent photographs may be taken at night.

A home-made blowpipe.



Experiments can also be made with blocks of magnesia, zinc oxide, oxide of zirconium and compounds of these and other infusible oxides, all of which will give a brilliant light of varying color generally without fusing. Dissimilar metals can be joined in the form of wire without special fluxes. Should a flux be required, borax answers the purpose very well, or boracic acid. The fusing together of different metallic oxides by the aid of boracic acid flux will often produce excellent imitations of precious stones.

An excellent illustration of the explosive properties of a mixture of oxy-hydrogen gas can be shown by blowing soap bubbles with the blowpipe, and allowing the bubble to float in the air; then apply a lighted taper. The report upon ignition will be deafening. A soap bubble blown at the tip of the blowpipe, and the gas supply cut off will act in the same way, but it is better if it be allowed to float in the air.

The Standard Black

By A. L. Hodges

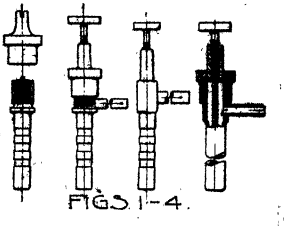
The question often arises, What is pure black? Teachers of physics say that black is an absence of all color—that is, no matter what light falls on a pure black substance none will be reflected, all being absorbed. There is no such substance known to man which will do this thing but, as usual, ingenuity has overcome this disadvantage. The standard of blackness and, than which none can be blacker, is simply a hole in a black box. The physical reasons for this are easy to see. The only condition necessary is that a minimum number of rays of light shall be reflected from the standard of blackness. To show the advantage of the hole we will contrast the rays reflected from the black face of the box with the number coming out of the hole. Let a ray beam of light strike the face and hole normally or obliquely. The face at once shows itself lighter than the hole for this reason: The rays striking the face are diffusely reflected in every imaginable direction and at every imaginable angle, consequently an eye in front of the face will receive a certain number of these diffusely reflected beams. But now consider the rays that go through the hole and that strike the back of the box (also painted black, and of a rough surface, as is the face). These will also be reflected in every imaginable direction and *for that reason* the majority of them will not come out of the hole but be caught on the inside of the face being either absorbed or reflected again. So if a fewer number of rays come out the appearance will be the more black to the eye, as the eye only "sees" when a ray of light enters it. Illustrations of this principle are common. If one looks into an open window of a house on a very bright day, even, the window looks simply like a black hole—the light getting in is not reflected back again in near the amount of entering, even though the inside wall be of the same color as the outside wall.

The extreme of blackness.

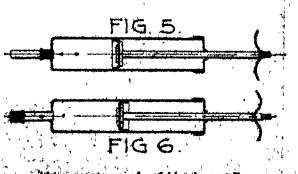
Air Apparatus for Amateurs

By John D. Adams

Compressed air has such a wide application to experimental work and in so many of the arts that it may not be amiss to point out the possibilities of ordinary bicycle supplies in this line of work.



Considering its cost, lightness, and simplicity, the ordinary ten-cent bicycle pump is a remarkable piece of apparatus. If we desire a moderate supply of compressed air to operate, for example, an air brush or a torch—it is only necessary to solder a bicycle valve to a suitable tank and connect our pump. But, you say, how are we to get the air out of the tank? In Figs. 1 to 4 is shown the method of converting a bicycle valve into a needle valve—and an excellent needle valve, too, because when it comes to holding air it is hard to beat a bicycle valve. It will retain air for months. The valve in Fig. 1 is drilled at the base of the threaded portion, and is provided with a small brass tube, fitted into the drilled hole and securely soldered. The cap is drilled through the top and threaded for a screw, which, when screwed far enough down, pushes the little valve stem down and thus lets the air escape. A very small leakage may occur around the rubber gasket in the cap, but this is negligible, as it occurs only when the air is being drawn. If cutting threads is an inconvenient operation, procure an ordinary nipple and spoke. File off the top of the cap, drill a hole in its top, fit on the nipple and secure it with solder. The resulting cap will then be as in Fig. 2. Cut off the threaded end of the spoke and solder on a round cap, so as to form a suitable screw.



The somewhat neater valve shown in Fig. 3 may be made by filing off all the threaded portion of the original valve and discarding the cap entirely. The small side outlet tube is provided as before, and the nipple is fitted and soldered directly into the top. The regulation of the air supply is very sensitive.

If three ordinary ten-cent bicycle pumps are arranged so as to be operated from a crank shaft with a fly wheel, we obtain a small triplex pump of good capacity and very uniform delivery. In such arrangements it will usually be found more satisfactory to make the delivery from the lower end instead of through the hollow piston rod, in which event the latter must be soldered up and the lower end provided with a suitable outlet tube. Where it is not practicable to have the valve attached to the air tank, solder it to the lower end of the pump, as in Fig. 5.

Fig. 6 shows the ordinary bicycle pump changed into a vacuum pump. The cup leather is reversed, the piston rod is closed, and a valve is soldered to the lower end in the position illustrated. It is hardly necessary to remark that such a pump will not produce a high vacuum, but it will compare very favorably with the best piston pumps, and will be found useful in many experiments requiring a greatly reduced air pressure.

Sometimes tin cans, such as groceries come in,

Air apparatus made of bicycle supplies.

will serve as air tanks, but if the pressure is rather high choose one having a length of two or more diameters and brace it by running some straight pieces of wood through and projecting beyond at the ends.

The Inventor's Department

Simple Patent Law; Patent Office News: Inventions New and Interesting

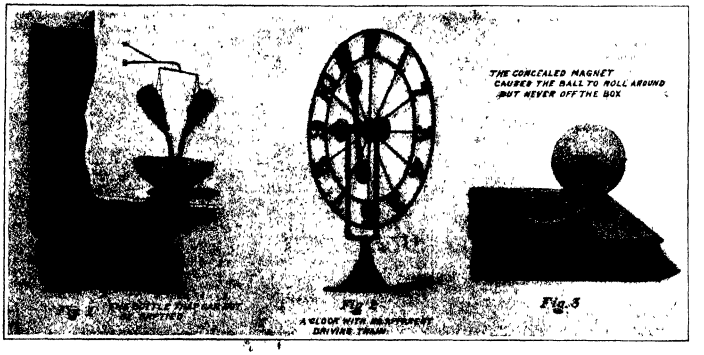
Mechanical Advertising Novelties

Of the many ingenious schemes employed in advertising, none have proved more effective than the various mechanical devices which various inventors have turned out from time to time. The public in general loves a mystery, and a device which apparently contravenes some general law of nature is sure to receive much attention. In Fig. 1 is shown an apparatus, recently patented, which has been quite successful as an advertising novelty. It consists of a bottle suspended in an inclined position and from its mouth there pours a constant stream of liquid into a tank. As there is no visible means for replenishing the liquid in the bottle, one would naturally expect it soon to become empty, but the level of the liquid in the bottle remains the same. Nature's laws, however, have not been upset, for in the center of the stream is a glass tube of the same color as the liquid and, hence, invisible. The lower end of this tube is connected with a pump and the upper end extends up into the bottle so that the pump is constantly withdrawing liquid from the tank and forcing it up into the bottle, whence it pours out around the glass tube, thus rendering it invisible. So perfect is the illusion, that no hint can be gained from a working device as to the secret of its operation.

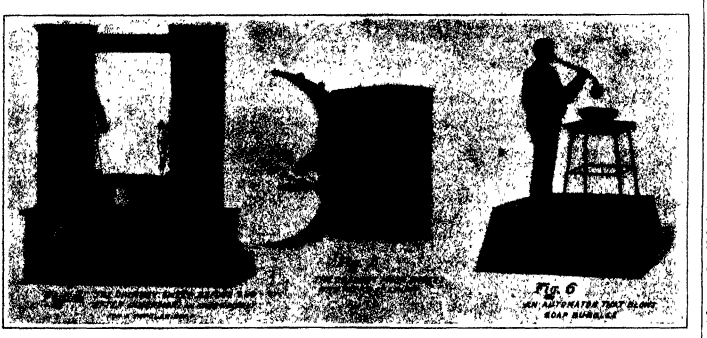
A clock, keeping excellent time and consisting of a plate of glass on which is painted a dial, a bolt passing through the center of the dial and forming an axis for hands, with no apparent place for a clock movement, will always attract much notice. Recently an ingenious jeweler in a West Virginia lumber town constructed one, using a pane of glass, and wood for the hands. Many a lumber jack spent hours conjecturing how it worked. It made no difference in which position the hands were placed, they would promptly revert to their proper position. The wooden hands were carefully covered with tinfoil, so as to conceal the watch movements inclosed therein. The balancing of the hands was accomplished by an ingenious system of shifting weights. A number of clocks of this type have been patented, one of the cleverest being shown in Fig. 2. The enlargements in the hands house the watch movements and the shifting counterweights.

Fig. 3 shows a clever apparatus for attracting attention. All that the spectator sees is a flat-topped box on which a large ball rolls round and round but never falls off. The force moving this sphere is invisible. The sphere is but a thin shell, and inside this shell is a small metallic ball which is free to move about the inner surface of the large sphere. Inside the box is a magnet which is rotated by a small motor. As the small ball endeavors to follow the magnet, it causes the large sphere to roll about the box lid.

For calling attention to the excellence of a certain brand of soap, the device shown in Fig. 4 was designed. This shows a very grimy figure descending from a chimney into a bath, from which he emerges clean and white. The two figures, however, are on opposite sides of belts which are driven by a hidden motor.



Most people imagine that the wooden Indian has a monopoly of the tobacco sign business, but he has a competitor in the dummy which ostensibly smokes a cigar. The cigar, however, is likewise a dummy and the smoke comes from a concealed pot of burning tobacco and is intermittently expelled from the lips of the dummy by concealed bellows. One of the most elaborate of these signs, which was recently patented, appears in Fig. 5. This is a hollow crescent figure, whose convex face is studded with incandescent lights, and bulbs are also arranged in the eyeholes and at the outer end of the cigar, held in the mouth of the figure. At the back of the figure is a box containing a small motor which operates mechanism for intermittently turning on and off the lights, and simultaneously with the turning on of the lights, to blow smoke out through the mouth of the figure.



The blowing of soap bubbles is an occupation usually accorded to children, but an automaton for doing this has been patented (see Fig. 6). This figure dips his pipe in a bowl of soap suds, then raises his arm and at the same time a current of air is turned on for blowing the bubble. Then the air is cut off and the fan, which is held in the other hand, is waved and the bubble is blown off into the air. The bellows and the mechanism for working the various levers and the valve are located in the box on which the automaton stands.

The combination of a flower and butterfly (Fig. 8), is designed for the display of precious stones. By means of a clock-work mechanism, a cavity in the flower is alternately opened and closed and at the same time the wings of the butterfly and the petals of the flower are moved.

Nothing is quite so comforting to a hungry man on a cold day as the steaming dishes of food displayed in the windows of restaurants. Many a dyspeptic has come to grief when a steaming dish of corned beef and cabbage has been brought to his attention in this manner. A close examination of the dish would have disclosed a cleverly concealed steam pipe, running from some distant boiler and discharging through the bottom of the dish like the coffee cup shown in Fig. 7. Fig. 9 shows how this idea has been utilized for displaying effervescent wines. The stem of the wine glass is hollow and in the lower end is placed a porous plug, through which air is forced by a concealed pump. The pressure must be small in order that the air may rise in minute globules, thus imitating sparkling champagne. A concealed reservoir is also connected with the hollow stem so as to keep the liquid in the glass at a constant level, for a considerable part of the liquid will be lost in evaporation.

The advertising value of novelties of this kind is unquestioned and one is surprised, in looking for patents on this art, to find that the number is so small. Their

MECHANICAL ADVERTISING NOVELTIES

cost of production is generally so small, compared with the huge and elaborate signs now in use, that it would seem that inventors would find this a profitable field of endeavor

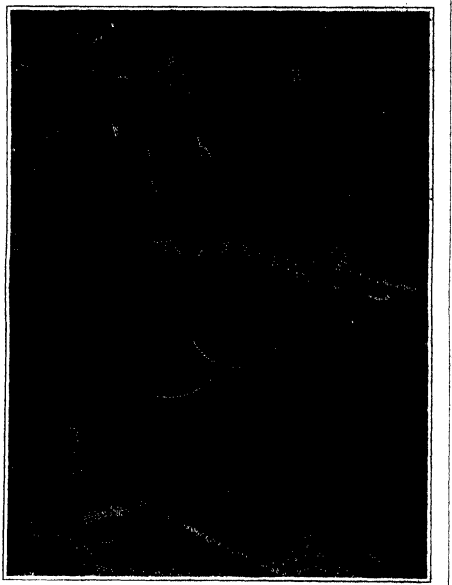
A Fireman's Smoke Protector

By Herbert T. Wade

IT is a popular fallacy that a fireman can be trained to endure almost any degree of smoke, thanks to the frequent use in the daily press of such terms as "smoke eaters" Beyond certain limits even the fireman is unable to withstand smoke, and it interferes greatly with his fighting fires at close range, especially in cellars Consequently, for many years there has been a demand for a practical smoke helmet or other device that would supply fresh air or oxygen to the fireman at work in an atmosphere impossible to breathe

Though they are used extensively in Europe and supplied to a number of American fire departments, such devices have never found wide favor in the United States, where they are regarded by many firemen as cumbersome and of limited utility Nevertheless, American firemen have been anxious to find suitable apparatus of this nature, and the investigations of mine rescue experts with such appliances have been observed with interest

The fireman demands a light weight device that shall be simple and reliable, ready at a moment's notice, yet easy to adjust and manipulate Under conditions where a line of hose may be used, this has been secured in a recent invention by James D Halloran of the New York fire department, which tested in actual service at a fire on September 19th, has been found to work with great success It consists of an auxiliary line of hose connecting with the outside air, through which pure air is drawn by the passage of the water through the nozzle of the main line of hose, and distributed by means of tubes connecting with a rubber piece covering the nose and mouth of the fireman like the nose guard of the football player The device involves a cylindrical brass piece or collar, which is screwed on the end of an ordinary control nozzle, such as is found in the equipment of any hose wagon. To this is attached a brass pipe about three feet in length which opens on the main bore, through which the stream passes, and connects with the air supply hose already mentioned. From this brass pipe are taken three flexible pipes which terminate in the rubber face pieces held by the teeth



When the water in the main line of hose passes through the nozzle it sucks or draws the air from the outside through the small hose, so that it is available in abundance for breathing through the flexible pipes, so long as the water is flowing The principle is very much the same as the familiar water-blast pump of the laboratory, and the application seems to be no less successful Its particular usefulness will be in cellar fires, where dense smoke is usual and gives great trouble to firemen Here combustible rubbish is responsible for many serious fires, which often could be more promptly extinguished were the firemen able to get directly at the seat of trouble, instead of being forced to use cellar pipes directed from above

It is of further interest that this new device was supplied to a double section hose company in the high pressure district whose equipment now represents the last word to be said in fire department practice, and to this organization also has been assigned the fireman inventor This company has to deal with many cellar fires and the new smoke protector will not only have the surest possible trial but will be greatly appreciated by the firemen themselves Changing conditions in fire fighting demand improvements in apparatus and methods, and the mechanical training now being received by firemen is bound to produce many ingenious inventions, of which Mr Halloran's smoke protector is a sample.

Notes for Inventors

Aluminium Pulleys.—One of the big machinery concerns of this country recently made some pulleys of aluminium to meet some special conditions required by one of its patrons and the innovation proved to be such a desirable one that more were made at once and now they have been adopted as standard by that particular concern They are said to have many advantages over those of cast steel. It is necessary to make some slight departure from the usual shape but this is a very trivial matter

The Telautograph in Desks.—Telautograph machines, which reproduce a written message at more or less distant stations, have been introduced into desk drawers, for use by bank presidents and public men, enabling the latter to make inquiries of clerks and secretaries without the knowledge of the caller It is possible to write a message under these conditions and receive an answer concerning the personality or business of the individual seated at one's elbow, without leaving the desk or seeming to make any inquiries

A new device for enabling firemen to enter smoke-laden atmospheres.

A Striping Machine.—Striping is a branch of the painter's art which requires special qualifications and the man who has a reputation for good striping has no fear of losing his job Carriages, motors, machinery, farming implements and a great variety of similar articles are not regarded as properly finished if they are not striped This has always been done by hand, the painter using a long haired brush, but the greatest essentials to the work is a steady hand and a good eye. Thus equipped, he becomes so expert that he makes a straight line better than others do with a straight-edge. A hand device has been recently invented for performing this work, and it greatly facilitates the task for the reason that the painter is enabled to do twice as much work in a given time The apparatus is designed on the principle of the fountain pen. It fits in the palm of the hand and is supplied with a bulb by which the flow of paint is controlled A number of interchangeable wheels are supplied with the striper and with these it is possible to make a great variety of stripes as well as small borders, such as walls of Troy, oak leaves and similar designs.

A Safety Device for Trolley Cars.—A trolley car which cannot start while a passenger is in the act of alighting or boarding the car has been in experimental use for a short time at Portland, Me. Such a feature will prevent most of the accidents which railway companies are compelled to pay damages for, and if successful, will meet with immediate adoption wherever the open end cars are used. The invention consists of a hinged step which is depressed a distance of a half an inch by a weight of less than ten pounds. This depressed position of the step has the effect of breaking an electrical circuit connected with the contractor and the latter fails to close by any act of the motorman while there is any weight on the step. The same principle has been applied to the elevator which will prevent that kind of accident which is so common, that of the car starting when a person is just in the act of entering it, the prospective passenger being crushed between the car and the wall of the building. A section of the elevator floor at the entrance yields slightly under the weight of a person and this throws into action a safety device which prevents the starting of the car.

Bricks That Float.—At the present time there is no particular demand for a brick that will float but such a thing will be regarded as a curiosity the world around. In the development of a special brick, designed to be used as an insulation in the construction of cold storage plants, breweries and refrigeration plants and is meant to take the place of cork, flax, charcoal fiber and sawdust, all of which are imperfect insulating materials, the use of which is attended by foulness and rot or are otherwise offensive. The brick, in waterproofing, is so burned that 45 per cent of its volume is confined air, with the result that one of these bricks being cast upon the waters, will float along like a block of wood.

A New Letter Box.—The latest suggestion for letter boxes is one made of pressed steel, without any ledges or places in which a letter might become lodged in its interior. This is a trouble which exists despite the greatest care. Many letters are delayed or fail of delivery entirely by being caught inside the letter box and securely held there. Another feature of the new box is that it has a drop bottom, which is almost as great a consideration to the postal authorities as the smooth interior, for it permits a box filled with hundreds of letters to be emptied as quickly as another containing but a few letters The carrier's receptacle is swung under the box and the bottom opened so that all letters drop at once down into the bag without any possibility of loss or delay.

Another Worthington Pump Patent Expires.—The patent to Charles C. Worthington, No. 526,429, having issued September 25th, 1894, expired on September 25th, 1911. This patent involves the gradual closing of the valves at the end of the plunger stroke and enables a pump to be driven by a direct-acting steam engine with an increased velocity and avoids wear and tear upon the valves by slamming. Worthington has later patents still in force among which are Nos. 584,533, 584,534, No. 607,902 of July 26th, 1898, and No. 657,976 of September 18th, 1900. The original Worthington pump patent, No. 24,838, was issued July 19th, 1859, to Henry R Worthington and included two direct acting pumping engines propelled by steam or other fluid and so arranged that each engine actuated the inlet and outlet valves governing the motive power of the other, thereby insuring the constant action of at least one pump piston upon the water and relieving the action of the pump from shocks and concussions This was one of the most important pump patents ever issued and the invention was a valuable contribution to the art to which it relates.

Metal Cloth.—An entirely new product, which takes up a position about midway between artificial silks and the fibers hitherto known which have been made from metal, has just been placed upon the German market by a well-known Elberfeld firm. In contradistinction to the metal fibers so far known, Renar yarn does not consist of a metal core or man-thread spun round with tinsel, it is a core, made of any suitable medium which, by means of a special chemical process, is entirely covered with a metallic coating which becomes thoroughly incorporated with the core. At the same time all the metallic lustrous particles are so embedded in the external coat that they are protected against atmospheric or other extraneous influences, and thus maintain their sheen or luster for an indefinite period. The yarn is not only produced in the original colors of gold, silver, copper, old gold, etc, but is supplied in any modern shades required; all these colors are characterized by a fine, striking metallic luster which will not fail to please, and which are reminiscent of silk and metallic lustrous combinations. The yarn can also be worked up with artificial silk From experiments made, it is fully proven that this new yarn is perfectly "fast;" that is to say, it retains its color and never gets black or oxidized.

Patents to Former Examiners.—Among the patents issued on August 15th, 1911, is one, No. 1,000,414, to Charles J. Kintner of New York city, for a hose connection, and another, No. 1,000,476, to Oscar Woodward of Montclair, N. J., for a typewriting machine. Both of these inventors were formerly principal examiners in the United States Patent Office, and a patent, No. 1,000,425, for a valve, was issued on the same day to Edward N. Pagelsen of Detroit, Mich. Mr. Pagelsen was also, at one time, a member of the examining corps of the Patent Office.

RECENTLY PATENTED INVENTIONS.

Interesting items are given to all patentees. The specifications are obtained by special arrangement with the inventors. Terms on application to the Manufacturing Department of the SCIENTIFIC AMERICAN.

Dressmaking to Apparel.

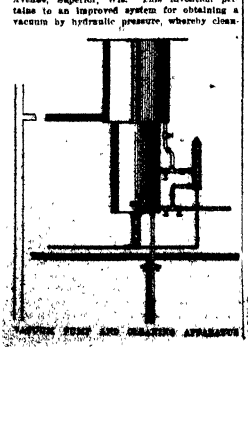
COMBINED SCARF, SHAWL, AND SWEATER.—J. ADLER, New York, N. Y. This invention relates to clothing, and the object is to provide a wrap which may be used as a shawl or scarf, and when desired may be readily converted into a sweater. The combined scarf, shawl and sweater may be manufactured at very little expense and may be conveniently used in a number of ways to protect the body of the wearer.

Of Interest to Farmers.

COMBINED LISTER, PLANTER AND RIDGE BUST.—SAMUEL B. HAMILTON, R. 2, Wakefield, Kan. This inventor provides a mechanism which may be adjusted to space the operation of a lister plow to form parallel ridges; provides a frame for an implement of the character specified, having strength, lightness and durability; provides carrying wheels

COMBINED LISTER, PLANTER AND RIDGE BUSTER

arranged to cause the wheels to track toward the center of furrows, to form a revolving wedge the rearward spread whereof bears against the sides of furrows and prevents the drift of the wheels and implement, and provides a simple, durable and economical frame structure. The illustration shows a perspective view of the implement, constructed in accordance with Mr. Hamilton's invention.

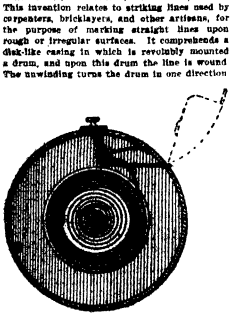


SPRING GUARD ATTACHMENT FOR CORN HARVESTERS.—J. H. BAEHR, Eden Valley, Minn. The invention provides an attachment which may be secured directly to the under side of the dividers, which is in the nature of a spring guard for preventing inclining of the stalks in their movement toward the binder table, or rather for holding them in vertical position. It may be attached to the under side of dividers of ordinary corn harvesters without interfering with the working parts thereof

Of General Interest.

MOLD FOR MAKING CONCRETE ARCH BLOCKS.—W. C. HOLMES, Scarboro-on-the-Hudson, N. Y. In the present patent the object of the invention is the provision of a new and improved mold, more especially designed for making arch blocks, and arranged to permit convenient adjustment of the mold parts for making blocks of different sizes for arches of different spans.

DISPLAY CARTON.—A. M. BOOS, Boston, Mass. This invention relates to display cartons, and has reference more particularly to a device, comprising a back, sides, a front, a top having an opening to receive the articles to be displayed, and an inclined bottom having gaps adapted to engage the lower ends of the articles, to assist in holding the same in position.



VACUUM PUMP AND CLEANING APPARATUS.—L. L. MONTGOMERY, 3506 Oaks Avenue, Superior, Wis. This invention pertains to an improved system for obtaining a vacuum by hydraulic pressure, whereby cleaning by vacuum may be accomplished, and which may be reversed to form, to a certain extent, a hydraulic air-compressing pump. A further object is to provide a system in which hydraulic means creates a vacuum or pressure, with means for automatically controlling the hydraulic means by the vacuum or pressure created. The device is simple in construction and inexpensive to manufacture, and is illustrated herewith in vertical section showing a fragmentary portion of the system in operation

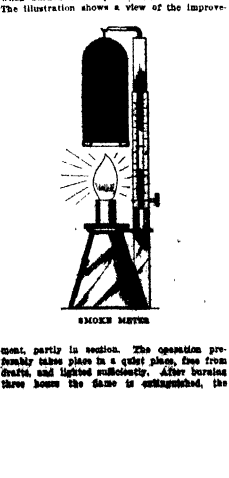
VACUUM PUMP AND CLEANING APPARATUS

Hardware and Tools.

STRIKING LINE.—HENRY K. KING, 214 E. 20th Street, Manhattan, New York, N. Y. This invention relates to striking lines used by carpenters, bricklayers, and other artisans, for the purpose of marking straight lines upon rough or irregular surfaces. It comprehends a disk-like casing in which is revolubly mounted a drum, and upon this drum the line is wound. The unwinding turns the drum in one direction

STRIKING LINE

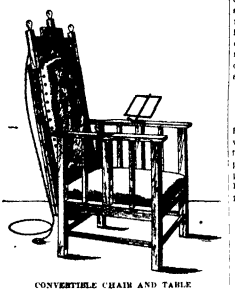
the drum being retracted by a spring. The casing is provided with a sector-like opening and fitting into this opening is a hollow door through which the line is drawn, and disposed within the hollow door is the inking apparatus. This patent is for sale. The device is illustrated herewith and is shown in perspective ready for use, the line being partially unwound



HOSE COUPLING.—FRITZ A. SCHNEIDER, 403 E. 125th Street, Bronx, New York, N. Y. The object here is to provide a coupling, arranged to permit quick coupling and uncoupling of the members, at the same time insuring a tight joint with a view to prevent leakage when the members are coupled. For this purpose use is made of coupling members, of which one is provided with a bayonet slot, and a spring-pressed locking device mounted to slide on one of the coupling members and provided with a key adapted to engage key-ways standing at an angle to the slot and stud. The plan view of the hose coupling as applied is pictured in the engraving

HOSE COUPLING

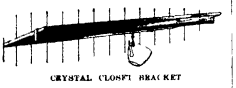
Heating and Lighting.



SMOKE METER.—FRANKLIN W. MANN, Franklin, Pa. This device determines the amount of unconsumed carbon in illuminants when burned under predetermined conditions. The illustration shows a view of the improvement, partly in section. The operation presumably takes place in a quiet place, free from drafts, and lighted sufficiently. After burning three hours the flame is extinguished, the mantles removed, and brought to normal temperature, preferably in an exsiccator, as is also the reservoir and the remainder of unconsumed oil. The reservoir and unconsumed illuminant are then weighed separately to ascertain the exact amount of illuminant consumed, and the net weight of unconsumed carbon is found by the difference in weight between the mantles before and after use

SMOKE METER

Household Utilities.

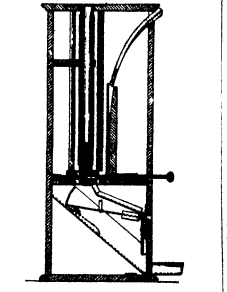


CONVERTIBLE CHAIR AND TABLE.—ISRAEL HOFFMAN, 85 Lenox Avenue, New York, N. Y. The invention provides a convertible chair and table, arranged to permit of conveniently and quickly changing the table into a chair and vice versa, and when in the form of a chair a book rest is provided for reading purposes, electric lights for the proper illumination of the reading matter and a receiver for

CONVERTIBLE CHAIR AND TABLE

cigar or cigarette ashes, burned matches, etc. The frame has arm rests, chair seat, combined chair back and table top provided with means to swing the back and table top onto the top of the arm rests, to provide a table or to swing it into position to form a chair. The accompanying illustration shows the convertible chair and the table set up to form a chair.

CRYSTAL CLOSET BRACKET.—RACHEL JAFFE, Borough of Manhattan, New York, N. Y. The accompanying engraving is a perspective view of this invention applied to a glass shelf. The invention relates to a new and improved form of depending bracket, and is particularly adapted to form a bracket for

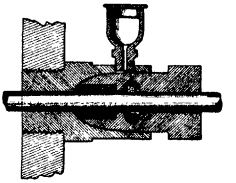


CRYSTAL CLOSET BRACKET

a glass shelf such as used in crystal closets where it is inconvenient or impossible to attach a supporting means for the bracket directly to the glass. By means of her improved bracket, a means is afforded whereby cups or other articles may be suspended beneath the glass shelf without in any way interfering with or modifying the construction of the glass shelf

Machines and Mechanical Devices.

CHANGE MAKING MACHINE.—JOHN R. CONRAD, Canajoharie, N. Y. Through a slot



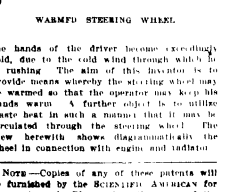
CHANGE MAKING MACHINE

in the machine the coin to be changed is introduced and will fall to a position in front of a plunger to operate a slide when the plunger is actuated, the slide having an opening therethrough adapted to register with the coin cylinder above an opening in the partition on which the slide rests, so that when the opening in the slide registers with the cylinder, coins will descend and rest on the partition, and when the slide is moved relatively to the partition, coins within the opening between the planes of the slide will be moved with the slide until the opening therein registers with the opening in the partition, when coins will fall through the last mentioned opening. A perspective view of the machine is pictured in the engraving

CHECK CONTROL STAMPING MACHINE.—PETER LAMBERT, 161 West 54th Street, New York City. This invention is comprehended in a receptacle adapted to receive mail matter, the receptacle being provided with means for stamping the serial number, together with the hour and date of mailing, and an inscription stating that the required amount of postage has been paid. The object of the invention is to provide a mail box adapted to receive the proper amount of coin for postage when the matter to be mailed is inserted in the box, it being especially adapted for use under the control of the government in public places, thereby providing for considerable saving in the selling of stamps and the handling of mail matter

Prime Movers and Their Accessories.

STUFFING BOX.—LOUIS CIRAC, care of Hon. D. C. McDonald, Ely, Nevada. This invention is an improvement in packing or stuffing boxes for use on piston rods, valve rods, pump plungers or other similar devices wherein packing is utilized to surround a rod or the like, and the invention has for its object the provision of a simple construction which can



STUFFING BOX

be easily operated to compress the packing and secure a proper packing of the joint and by which lubricant may be supplied directly to the packing through openings in the devices for compressing the packing. It provides efficient lubrication, convenient renewal of the packing and a ready adjustment of the parts whenever necessary or desired. This invention as in use is shown in the engraving in longitudinal section

Pertaining to Vehicles.

WARMED STEERING WHEEL.—EDWARD F. REICHERT, Jr., Room 212, 1547 Broadway, New York, N. Y. This invention refers to a steering wheel with appliances for warming the same so as to keep the operator's hands in a comfortable condition. It is well known that in the case of launches, aeroplanes, or in open automobiles without protecting wind shield,

WARMED STEERING WHEEL

the hands of the driver become exceedingly cold, due to the cold wind striking which he is rushing. The aim of this invention is to provide means whereby the steering wheel may be warmed so that the operator may keep his hands warm. A further object is to utilize waste heat in such a manner that it may be circulated through the steering wheel. The view herewith shows diagrammatically the wheel in connection with engine and radiator.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

NEW BOOKS, ETC.

RESEARCHES ON THE EVOLUTION OF THE SOLAR SYSTEM. Vol II By Prof T J J See. 1910 735 pp, 4to; 57 full-page insert plates

In place of Laplace's theory that rings of vapor were once thrown off from the sun to form the planets, and from the planets to form the satellites, Prof. See offers us his capture theory Instead of regarding the planets as gradually detached from the sun and set revolving in approximately circular orbits Prof See endeavors to show that the planets have developed from small nuclei originating in our nebula, at a great distance from the sun, and that their orbits have since been reduced in size and rounded into almost perfect circles by moving in a resisting medium If that idea is true the planets were never part of the sun, and Laplace's ideas are wrong Similarly, Prof See endeavors to show that satellites now revolving about the planets were originally independent bodies moving in regular elliptical orbits about the sun, but that they were afterward captured and made satellites by dropping in toward the planets about which they now revolve An existing medium in the form of cosmical dust is assumed to be responsible for the capture of the satellites The effects of repulsive forces in nature are dwelt upon in this volume even to greater extent than attractive forces Heavy bodies drifting toward powerful centers of attraction under the action of gravitation alone are assumed to pass into smaller and rounder orbits, with each revolution, by moving in this resisting medium Light bodies of small mass, in the form of fine cosmical dust are driven away from the stars by repulsive force and thus lead to the formation of nebulæ In remote regions of space Accordingly, the repulsive force at work in the stars scatters the dust to form the nebulæ, the condensation of the nebulæ forms the stars, so that a cyclical process is at work in the universe, the nebulæ producing the stars and the stars in turn reproducing the nebulæ Adequate analysis of Prof See's work can be undertaken only by an astronomer who takes the trouble to check up his calculations He has a daring piece of theorizing on the basis of modern discoveries and mathematical calculation, Prof See's book must certainly command respect It cost him four years of hard work to produce it a fact which is amply demonstrated by its size

THE CONQUEST OF THE AIR By Alphonse Berget G P Putnam's Sons, 1911 249 pp Numerous Illustrations

This second edition of Prof Berget's book has been considerably re written in the effort to bring it up to date That effort has not been altogether successful We learn, for example, that the Wright machine still starts on rails, although, as a matter of fact, the Wright machine has for some time been running on wheels like most biplanes and monoplanes Apparently, the Wright brothers count for very little as inventors with Prof Berget He regards them as mere imitators of Chanute and Lilienthal, and he credits Blériot as the real inventor of the man-carrying aeroplane We learn with some astonishment that the Wright machine owes its success entirely to the remarkable skill of the Wright brothers as pilots, although the author does not point out wherein the operation of a Blériot or any other machine with warping wings is easier The part played by such men as Maxim and Langley in the development of flying machines is not sufficiently apparent Indeed, the chief criticism we have to make against this book is the spirit of French jingoism in which it is wrought This applies not only to the discussion of the flying machine, but to the discussion of the dirigible as well If the reader can overlook these faults, he will find here a good deal of sound aeronautical and aviation principle laid down in a straightforward way which cannot but prove instructive to the man who knows nothing of the subject The translation we regret to state is not altogether idiomatic and is evidently done by someone not thoroughly familiar with the subject

THE PRINCIPLES OF SCIENTIFIC MANAGEMENT By Frederick Winslow Taylor, M E, Sc D New York Harper & Brothers, 1911 Price, $1.50 net

These much discussed principles are the fruit of Mr Taylor's thirty years of experience and experimenting Briefly, his claims are that by the discovery of the laws governing labor fatigue and rest and by the science application to well planned tasks, he is able to double and quadruple the output of his men without pushing them to the point of exhaustion For example a man who under the old conditions loaded 12½ tons of pig iron per day, now transfers 47½ tons from the pile to the car In the case of shovelers, the determination of the shovel load is a question of prime importance and with each different occupation there enters new factors that must be painstakingly weighed and reduced to scientific formulæ In the face of much shrewd criticism, Mr Taylor has no less shrewdly defended his position and his theories There is little doubt that his discoveries inaugurate an era of vastly improved methods, particularly among the heavier occupations It will be found impossible, however, to reduce the more complex human activities to exact formulæ without destroying to a certain extent the spontaneity, the elasticity, which comes of man's sense of personal mastery and freedom To use an illustration from athletics, no two jumpers clear the bar in exactly the same way, and to force one method upon all tyros would soon reduce the number of potential champions So long as the installation of the new methods is intrusted only to capable organizers, and a sufficient margin of safety is maintained to allow the varying personal equation, the spread of these principles of scientific management will be attended only by gratifying results

HISTORY OF THE SHERMAN LAW By Albert H Walker of the New York Bar New York The Equity Press, 1910 8vo, 320 pp Price, $2

The writer characterizes the Sherman Law as a latter day Magna Charta, a defensive weapon by which the craft of the well-in trenched minority should be shorn of its power to dictate prices on the products necessary to the life of the exposed and helpless majority Never before has the history of this Law's birth, its fight for life, and its final victory been presented in this compact and well condensed yet adequate form It makes a readable chapter in our history that should be welcomed by all who have the welfare of the nation at heart Thousands of speeches, arguments, and decisions have been taken by Mr Walker and boiled down until the substance of them all is given, and well given too, within the space of some three hundred pages

OUR HOME CITY By William Arthur, Omaha, Nebraska William Arthur, 1911 12mo, 133 pp Price, 25 cents

This is the description of an ideal city from the author's point of view His proposal is that a thousand families shall own their site at agricultural prices, each family building on land leased from the city The city keeps the title to all land, and owns and operates all public utilities A plan of such a city forms the cover design of the booklet and presents a lay-out that combines symmetry with accessibility and convenience

LOMBROSO'S CRIMINAL MAN By Gina Lombroso Ferrero New York and London G P Putnam's Sons, 1911 8vo, 332 pp Illustrated

Lombroso's criminological theories gave penology a new twist More and more we are beginning to regard the criminal not as a savage whom civilization has failed to tame, but as a diseased personality, a subject for the hospital rather than the prison The book before us is by Lombroso's daughter, Madame Gina Lombroso Ferrero, a lady who has done not a little psychological research on her own account and is therefore peculiarly well fitted to present a book on her famous father's criminological investigations Madame Ferrero's book, judging from the text, is intended primarily for the thoughtful reader who has no particular scientific training but who wishes to keep abreast of the scientific times For such a reader the book seems eminently well qualified Prof Lombroso has read the entire manuscript before his death and prepared an interesting introduction in which he traces the manner in which he conceived his theory of crime

ELEKTRO HEMISCHE UMFORMER By Johannes Zacharias Vienna and Leipzig A Hartleben, 1911 261 pp

This book is a very good review of the progress which has been made in the manufacture of galvanic current producers and their application

DAS SCHICKSAL DER PLANETEN. By Svante Arrhenius Leipzig Akademische Verlagsgesellschaft, m b.H A Hartleben, 1911

This is a reprint of Prof Arrhenius's essay on the Atmosphere of planets in Ostwald's "Annalen der Naturphilosophie" Arrhenius's conclusion may be thus summarized As the magma cooled a solid crust was formed Not until then was there an atmosphere or a planetary interior From the interior of the planet, gases particularly steam and carbon dioxide, exuded and arose to the highest levels of the atmosphere On this highly absorbent nascent atmosphere which flew above the clouds, sunlight reacts photo-chemically Because of the low temperatures of these upper layers, there is a great preponderance of photo-chemical reactions which are not appreciably affected by cold As the result of these photo-chemical reactions, and as a result of the ordinary reactions which occur later, oxygen and carbon dioxide are formed Both gases in the original atmosphere as hydrogen, hydrocarbons, which predominate in the outer layers of celestial bodies are gradually consumed by oxygen, so that finally, besides oxygen, only a few chemically inert gases remain such as nitrogen Steam and carbon dioxide, however, will continue to permeate the atmosphere through crevices in the planetary crust It was under these circumstances that life first developed This is the condition of the earth, and possibly of Venus. Gradually the thickness of the crust increases, gradually the waters evaporate, gradually volcanic action ceases, gradually the surface of the planet is transformed into a desert, gradually vegetation dies away, gradually oxygen ceases to be produced, gradually, in a word, the living planet becomes a dead world

THE PRINCIPLES OF AEROPLANE CONSTRUCTION By Reukin Kennedy, C.E. New York D Van Nostrand Company, 1911 137 pp Price, $1.50.

In this excellent book Mr Kennedy has explained the principles of the aeroplane, and put in concise form the elementary laws of mechanics and the inclined plane which govern its construction Formulæ are presented for the determination of the principal dimensions of the aeroplane in its simplest form, with numerical worked out calculations with the two systems in use.

KOMETEN UND ELEKTRONEN By Augusto Right, Leipzig Akademische Verlagsgesellschaft m b H , 1911

In this admirable little monograph, Prof Right has applied the discoveries of the English school of physicists, who have given us the electronic theory, to the phenomena of comets Radiation pressure alone is not sufficient to explain many of the vagaries of a comet's tail But the application of the electron theory undoubtedly helps considerably to clear away many a mystery The last chapter in the monograph is devoted to the consideration of the passing of the earth through the tail of Halley's comet, on May 19th, 1910

FLYING MACHINES TO-DAY. By William Duane Ennis New York: D. Van Nostrand Company, 1911. 205 pp ; numerous illustrations. Price, $1.50.

Prof Ennis has written one of the most sensible books on flying machines that we have seen The title of his work, to be sure, is rather misleading, for he discusses lighter-than-air craft as well as aeroplanes. Written primarily for the layman, the book sets forth the principles of the aeroplane and the dirigible with such clearness that a man of average education ought to be able to understand the explanation It is difficult, of course, for a work on aviation to be strictly up-to-date, for the art progresses so rapidly that improvements are made almost from week to week Still, it must be said that the author made a commendable effort to keep his reader informed of the more recent progress in flying machine construction

THE UNIVERSAL RAILWAY MANUAL 1911. Containing Valuations of the Principal British, American, and Foreign Railway Stocks Edited by Capt L. E. Hopkins, R.E London: Society of Railway Stock Holders New York The Macmillan Company 12mo., 598 pp Price, $2.50 net

This valuable book is based on the company valuations, reports of government statistics, etc There is also a considerable free criticism as to the financial position of companies, which is rarely distinguished The work has been done in the most admirable manner, and the book is one of the best compendiums of financial information that we have ever seen The maps and diagrams are particularly clear, and the index which should be in the library of every well informed person Railway systems of the world form a most fascinating subject

CHARTS OF THE ATMOSPHERE FOR AERONAUTS AND AVIATORS By A Lawrence Rotch, S.B., A.M., and Andrew H. Palmer, A.M New York. John Wiley & Sons, 1911

This book of Prof Rotch's is the first attempt made in this country to collect for the use of the aviator and the aeronaut in a readily understood form, the vast amount of data which have been accumulated at the Blue Hill Meteorological Observatory, one of the pioneer institutions of its kind We believe that somewhat similar work has been done in Germany and Italy The book consists of a series of charts which gives the relative heights attained by various aerial vehicles, atmospheric density and temperature, average temperature, barometric pressure, wind velocity, and pressure up to 30,000 feet, maximum wind velocities and pressure up to 30,000 feet at Blue Hill, wind pressures for constant velocities up to 30,000 feet, wind pressures for constant velocities up to 10,000 feet, monthly temperatures up to 12,000 feet at Blue Hill, monthly rain up to 12,000 feet at Blue Hill, hourly wind velocities up to 10,000 feet at Blue Hill, frequency of constant wind velocities, 1,000 to 10,000 feet at Blue Hill, frequency of winds at Blue Hill, 650 feet, velocity of winds at Blue Hill, 650 feet; frequency of winds at Blue Hill, 1,650 feet; velocity of winds at Blue Hill, 1,650 feet; frequency of winds at Blue Hill, 3,300 feet; velocity of winds at Blue Hill, 3,300 feet; frequency of winds at Blue Hill, 6,600 feet; velocity of winds at Blue Hill, 6,600 feet; frequency of winds at Blue Hill, 10,000 feet; velocity of winds at Blue Hill, 10,000 feet; wind velocity and direction up to 18,000 feet at St. Louis, winds at various heights as related to barometric pressure at the ground; frequency of winds in the N. E. trade region of the Atlantic Ocean, velocity of winds in the N. E trade region of the Atlantic Ocean; aerial routes in summer across the North Atlantic Ocean. Each chart is accompanied by simply-worded explanations, which will enable the aeronaut and the aviator to appreciate the significance of the facts conveyed by the charts.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12542) H. S. D. asks: Have you any publications regarding the making of ice by the vacuum process? I have placed a small amount of water under a bell jar with some sulphuric acid and have exhausted the air. The water cools but fails to freeze According to theory, should water freeze under the above conditions? Can you suggest any method for freezing water under the vacuum? A. The experiment of freezing water under a bell jar of a common air pump is a very difficult one The vacuum is usually too low. The metal of the pump is too good a heat conductor Water nearly as rapidly as the evaporation takes it out of the water. With a quick-acting high-grade pump, and by protecting the glass in which the water is contained from the metal of the pump, the freezing of the water will occur, but not rapidly. A very small and broad bell jar must be used. The sulphuric acid must be in a broad dish. The water is usually in a flat watch glass over the acid, supported by a wire frame which rests upon the glass dish in which the acid is put. The older books of physics usually have pictures of the arrangements. You will find it in Deschanel, Vol II, as well as the picture of Carre's apparatus for freezing water in bottles by the same method, which was once largely used, but has now gone out of use.

(12543) F K. writes. Occasionally I see mention made in your valuable journal by writers claiming to have seen ball lightning drop from the clouds, the accuracy of which is questioned by some and as being an illusion I distinctly remember one afternoon about 4 o'clock having seen such a ball drop from the clouds, was from a thunder cloud in the northwest sky I was facing the cloud at the time To me it appeared to be about six inches in diameter, and as it descended sparkled with short electric bristles until it reached terra firma. I was returning from a field at the time, and the distance between me and where it reached the earth to have been about half a mile This was at Centerhall, Pa I at once concluded when reaching the village to inquire whether the phenomenon had been observed there, and to my astonishment learned that "lightning had struck the house of Alex Shannon," followed the chimney down into the kitchen, where a little daughter was standing close to the range, and was instantly killed There was no other peal of lightning at the time, hence there can be no doubt that the ball lightning killed the little girl. The ball was about two and a half seconds in its descent A There was a time when the existence of a slowly moving globe of fire, a ball of electricity, which afterwards might explode with great force, producing all the effects of a lightning stroke, was denied and even ridiculed by scientific men We think all now admit the reality of these occurrences

(12544) W F M asks 1. Is iron or steel while very hot, or in a molten state, absolutely unaffected by magnetic lines of force? A Iron or steel above red heat cannot be magnetized 2 Will a thin sheet of iron held in front of the poles of a powerful magnet cut off all the "pull" of the magnet? A A thin sheet of iron will not cut off all lines of magnetic force A plate of sufficient thickness to furnish a path for the lines of force below saturation must be employed For a weight iron about 100,000 lines can be carried per square inch of cross section Even then there will be leakage into the air.

(12545) W. G M. asks. I have a pipe that leads from my well 14 feet higher than my sink I fill the pipe with water, and the water will flow from there to the sink, then stop I have put a pump on and sucked the water down and have the same trouble. I have to lift the water about 4 feet from the surface of the pipe there to go down. I would like to know the cause of its stopping, or how I can remedy it A The intermittent action you describe is inevitable with the simple siphon. Air carried into the pipe with the water escapes, as the pressure is reduced during the passage of the water up the pipe, and collects in the bend When sufficient air has accumulated, the water column breaks and the flow stops. Before the siphon can act, air must be removed by pumping it out or by refilling the pipe with water. These interruptions may be delayed by providing an air chamber at the high point of the siphon, so that the air may collect for a longer time before it interferes with the flow in the pipe. With a cock below the air chamber, and a plug or cock at the top, the whole air chamber may be filled with water whenever the collected air breaks the siphon's flow.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

Advertisements in this column are 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

BUSINESS OPPORTUNITIES.

YOUR FACTORY AT TULSA will command the Middle West. Natural gas power cost 25 to 35 H. P. per year. $200 buys site. Ample labor, materials. Direct oil and coal fields. On large river. Four trunk railways. Sixty-three thriving factories already. For further particulars write Industry, Bureau of Information, Tulsa, Oklahoma

GOOD BUSINESS OPPORTUNITY — For sale, a well established business, manufacturing and selling a specialty readily adapted into general use. A nice, clean, interesting business which can be expanded indefinitely. No special manufacturing experience necessary since present method and machine help can be retained. This is an exceptional opportunity for any young man who can command $4,000. Address "Specialty," Box 775 New York.

HELP WANTED.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business. Spare time will do. Previous experience unnecessary. All we require is honesty, ability, ambition and willingness to work a reasonable number hours. No soliciting or traveling. This is an exceptional opportunity for a man to put himself on record as a hustler. Write us quick for full particulars. Address Ernest E. K. Norden, Pres., The National Co-operative Real Estate Company, L.20 Norden Building, Washington, D. C.

WANTED.

WANTED TO COMMUNICATE with manufacturers of manufacturers agents, who can successfully handle latest press Cleaner. Patent No. 1,000,760. Address, E. L. Dahlstrom, San Diego California.

WANTED To communicate with manufacturers of iron goods to have on hand for sale, a patented article that can be used in hanging awnings, painting, etc., and costs $1.25 required for handling awnings by 50 per cent. Diagram will be sent upon request. Goldole, Box 713, New York

MISCELLANEOUS.

MOTORCYCLES CHEAP.—Send to-day for free catalog of new and used motorcycles. Also motorcycle accessories and astonishing motor outfits for converting bicycles into motorcycles. Shaw Manufacturing Company, Dept. 36, Galesburg, Kans.

MAKE BIG MONEY operating a Parcels Post Card Machine. Prize postal cards made and delivered in the spot in ten minutes in the open street. No days room necessary—a child can operate it. Experienced photographer to make first-class pictures. Parts at cost. Profits of 500 per cent. Write to-day for free booklet and instructions. Daygark Specialty Co., Dept. Y, St. Louis

FREE—"INVESTING FOR PROFIT" Magazine. Send us your name and I will mail you this magazine absolutely free. Before you invest a dollar anywhere—get this magazine. It is worth $10 a copy to any man who intends to invest $5 or more per month. Tells you how $1,000 can grow to $25,000 —how to judge different classes of investments; the best dividend payers of four centers. This magazine tells dozens how if you write to-day. H. L. Barber, Publisher, 426 W. Jackson Blvd., Chicago.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain articles listed and numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring to buy. There is no charge for the service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated. MUNN & CO., Inc.

Inquiry No. 9240.—Wanted, addresses of parties having for distribution of memorial containing poems in any form.

Inquiry No. 9247.—Wished, to buy a Pneumatic conveyor system.

Inquiry No. 9254.—Wanted, the name and address of manufacturers of fine enamels and pen holders, such as are used for marking on celluloid.

Inquiry No. 9263.—Wanted, to buy a patent touch-up device for use on lithographic stones, which will remove the grease on stone and apply powder.

Inquiry No. 9265.—Wanted, to buy a patent toilet-paper holder which will be manufactured on a royalty basis; to appeal to women and easily worked.

Inquiry No. 9266.—Wanted, addresses of parties making cement-lined water turbines.

Inquiry No. 9269.—Wanted addresses of parties making fuse elements or caps in any part of the world.

Inquiry No. 9270.—Wanted, to buy a machine for making wire hat frames.

Inquiry No. 9271.—Wanted, addresses of parties who manufacture or deal in the following: Cotton, cotton waste, cotton flannel, rags, cotton, or any material

The Harvest Moon

(Continued from page 804.)

angle of 66½ degrees to the plane of the ecliptic; and moreover the plane of the moon's orbit, which is inclined at an angle of a little over 5 degrees, has a retrograde motion, making a complete rotation in 18.6 years. The diminution of the retardation of the rising of the harvest moon is also variable, and dependent upon the latitude of the observer and the position of the moon's orbit. When the moon is midway between the nodes its direction of motion is parallel to the plane of the ecliptic. When it is at or near a node (which may be either ascending or descending) the direction forms an angle of about 5 degrees with the ecliptic.

The plot shows the positions of the earth (*E*) and of the moon at the dates of full moon—September 8th and October 7th; and also of new moon on September 22nd. The moon's orbit rotates in the direction of the arrow without the orbit; the arrow within the orbit is the direction of the moon's motion. Figs 1-4 represent the moon's orbit projected on a plane which is perpendicular to that of the ecliptic and parallel to the earth's axis. The scale is enlarged and shows the relative diameter of the earth and of the moon's orbit. *Fig.* 1 shows the plane of the orbit seen edgewise. In Fig. 2 the ellipse represent the orbit after one-quarter of a rotation. Fig 3 shows the plane of the orbit, again seen edgewise after one-half of a rotation. The ellipse Fig. 4 shows the orbit after three-quarters of a rotation. One-quarter of a rotation more brings the orbit back again to the position Fig 1. Fig. 5 is the position of the orbit in September of this year, and is situated between those shown at Figs 2 and 3. It is a view looking in the direction of the arrow *A*. In each of the illustrations the direction of the moon's motion is indicated by an arrow showing that part of the orbit which is near to, or farther from the reader.

Fig 6 is drawn to a very much larger scale, in order that the parallels of latitude on the earth's surface may be plainly visible, and to show some of the conditions which may affect the rising of the harvest moon. In order to bring the illustrations within the limits of the page, only a small part of the earth and two positions of the moon are included. The distance from *a* to *b*, and from *c* to *d*, show the average distance traversed by the moon in 24 hours, when it reaches the maximum distance above and below the plane of the ecliptic. If the positions *a* and *b* (below the ecliptic) were equidistant from *e* and from the earth's center, the moon would rise on consecutive evenings at exactly the same time to an observer situated very near *P* on the visible hemisphere. Also if the moon occupied the positions *c* and *d* (above the ecliptic) under similar conditions it would rise at the same time on consecutive evenings to an observer situated very near *P* on the invisible hemisphere. In the first case the plane of the moon's orbit passes through *a* and *b*: in the second it passes through *c* and *d*. In order to realize that the position of the observer in each case is near *P*, it must be remembered that the moon's distance from the earth is more than sixty times the earth's radius. The latitude of *P* is 66½ degrees (the polar circle). It is a well known fact that the harvest moon rises at or about the same time on consecutive evenings, in the north of Norway and Sweden. From an inspection of Fig. 6 it is evident that there would be a retardation at lower latitudes—as for example that of New York at *Q*.

When the plane of the moon's orbit is in the position corresponding to Fig. 1 forming a small angle with the equator; and the moon on consecutive evenings is at *f* and *g*, the retardation of the moon's rising is evidently greater than when the direction of the moon's motion is parallel to the ecliptic. When the orbit is rotated into the position corresponding to Fig. 3, and the moon on consecutive evenings is at *h* and *k*, the plane forms a larger angle with the equator, and the retardation is diminished. The illustrations might be extended indefinitely; but in general those here given show that in high latitudes the retardation is less than in lower latitudes, and that under favorable conditions at a high latitude, the moon may rise even earlier the second evening.

Fig 7 shows the plane of the horizon when the moon is above and below the ecliptic, and also the positions of the observer *p* and *p'* at the time of moon rise

Submarine Cables and Longitude Determination

(Concluded from page 806.)

strong enough to operate the electro-magnets. This cannot be done when the stations are connected by a long submarine cable, because the impulsive currents are too feeble to affect any but extremely sensitive receiving apparatus.

This difficulty has been overcome by Col. Bourgeois director of the geographical service of the French army, who was recently commissioned to devise a method of determining the difference of longitude between Brest, in France, and Dakar, in Senegal, which are connected by a cable about 2,800 miles long.

The receiving instrument employed in submarine telegraphy is the siphon recorder, invented by Sir William Thomson (Lord Kelvin). This instrument consists essentially of two very powerful electro-magnets between which is suspended, by two parallel fibers of cocoon silk, a small and light coil containing a great number of turns of very fine wire. The strength of the magnetic field is increased by a core of soft iron, fixed immovably inside the coil, which can turn freely without touching either the core or the electro-magnets. The coil, when no current is passing through it, is held parallel to the line of the magnetic poles by its bipolar suspension, but a positive or negative current causes it to deviate to the right or left from its position of equilibrium. A system of levers magnifies these movements and transmits them to a little glass siphon formed of a bent capillary tube. The short leg of the siphon dips into a vessel filled with a very fluid ink, and the long leg, which is drawn out to a fine point, moves transversely in front of a strip of paper, which is drawn along uniformly by clockwork. The ink is electrified by a small electrostatic machine and is therefore projected upon the paper in a continuous spray. When the siphon is at rest this spray marks a straight line parallel with the length of the moving strip of paper, but when the siphon is turned to right and left by the moving coil the result is a wavy line, the elevations and depressions of which correspond to the dots and dashes of the Morse code

Col. Bourgeois's method of determining longitudes by cable a double chronograph and a single siphon recorder are employed at each station. The chronograph is used to compare an auxiliary clock with the standard astronomical clock, while the siphon recorder is connected through a local battery with this auxiliary local clock and through the cable with the standard auxiliary clock of the distant station. Hence the jet of ink traces on the moving strip of paper a straight line interrupted by two series of indentations each representing intervals of a definite fraction of one second, the odd numbered indentations (for example) being made by the distant standard clock, and the even-numbered indentations by the local auxiliary clock, the error of which, with respect to the local standard clock, is known from the chronograph record. In the preliminary experiments it was discovered that the siphon recorder and the chronograph pen, both of which are connected with the auxiliary clock, are not equally quick in action, but as the difference is less than 1/100 second, it is of no practical importance. The indentations produced by the siphon recorder are less sharply defined than the marks made by the chronograph pen, but they are quite sharp enough for the determination of longitude.

A Radium Lode.—According to press dispatches, Dr. Douglas Mawson announces that he has discovered a valuable deposit of radium ore at Mount Painter, in the far northern district of the State of South Australia. According to his report, the deposit is of high grade.

Orient

GRAND CRUISE
To the Orient

By the most palatial cruising steamer afloat

S. S. "Victoria Luise"
(16,500 Tons)

Sailing from New York
JANUARY 30, 1912
on a 75 Day Cruise to MADEIRA, SPAIN, the MEDITERRANEAN and the ORIENT. Cost $325 and upward. The "VICTORIA LUISE" is equipped with every modern feature for luxury and comfort on long cruises

South America

Take a Delightful Cruise To South America

By the S.S. BLUECHER (12,500 tons) the largest cruising steamer sailing from one America to the other. Offers every luxury and comfort. Leaving New York Jan. 20, 1912. Ports of call: Bridgetown, Pernambuco, Bahia, Montevideo, Punta Arenas (through the Straits of Magellan), Valparaiso (across the Andes) Buenos Ayres, Rio de Janeiro, Bahia, Para, Port of Spain and St. Thomas. Optional side trips everywhere

Duration of Cruise 80 DAYS Cost $350 and up

West Indies

Five Delightful Cruises to the
WEST INDIES, PANAMA CANAL, VENEZUELA and BERMUDA

By the Popular Twin Screw S. S. are leaving New York

S. S. Moltke (12,500 tons) 28 days Jan. 25 Feb. 22, 1912 $150 and up
S. S. Hamburg (11,000 tons) 21 days Feb. 10, March 2, 1912 $125 and up
S. S. Moltke (12,500 tons) 16 days March 26, 1912 $85 and up

Every Luxury of Travel — Every Refinement of Service Insured

Italy and Egypt

SPECIAL TRIP by the superb transatlantic liner, Kaiserin Auguste Victoria, the largest and most luxurious steamer of the Hamburg American service. Equipped with Ritz-Carlton Restaurant, Palm Garden, Gymnasium, Electric Baths, Elevators. Will leave New York Feb. 14, 1912 for Madeira, Gibraltar, Algiers, Villefranche (Nice), Genoa, Naples and Port Said

Time for sight-seeing at each port. To or from Port Said $165 and up. To or from all other ports $115 and up.

For illustrated booklets descriptive of these cruises address

Hamburg-American Line

41-45 Broadway, New York

Fits the Figure Perfectly-Won't Shrink Always Springs Back to Shape

UNDERWEAR is a necessity—but Wright's Spring-Needle Ribbed Underwear is a *luxury* at the moderate price of a *necessity*—$1.00, $1 50, $2.00, for shirts or drawers, $1.50 to $4 00 for union suits; at all dealers

WRIGHT'S *Spring Needle* **Ribbed UNDERWEAR**

is a wonderfully *elastic* fabric, permanently *springy* Fits any figure perfectly, and keeps its shape under the hardest usage Very *durable* The Non-Stretching Neck (pat. appld for) ensures neck will always *hug snug*.

Made in fine Egyptian cotton, all wool, or mixed and in various colors. All weights for all seasons. If not on your dealer's send us his name and we'll see you are supplied

16 cts for leather threading samples of different fabrics

Supplement No. 1919. Order from your newsdealer or from *Munn & Co., Inc., 361 Broadway, N. Y.*

Aeronautics

The International Balloon Race.—Nine balloons are entered in the international cup race which starts from Kansas City on October 2nd. America will be represented by Lieut. Frank P. Lahm, Capt. John Berry, and Wm. F. Assman; France by Emile Dubonnet, Alfred Le Blanc, and Welby Jourdan; and Germany by Lieut. Vogt, Ingenieur Gerickes, and Freiherr von Pohl.

Exhibition Flights at Brighton Beach.—As we go to press the American Aviation Co. is about to conduct an aviation meet at Brighton Beach Race Track on the 8th, 9th and 10th inst Flights will be made by Grahame-White, in his speedy Nieuport monoplane, by Harry N. Atwood, Wm Beatty in their Wright biplanes, and Eugene Ely in his Curtiss biplane This is the first attempt to use the Brighton Beach Race Track for flying that has been made in some time, and it is hoped that it will meet with success and with the patronage of the New York public, as if this is the case, there will probably be more exhibition flights made there in the near future.

The Aviation Meet on Long Island.—The first big aviation meet to be held in the East opened on the 23rd inst. at the Nassau Boulevard aerodrome of the Aero Club of New York. Mlle. Helene Dutrieu, who pilots a Farman biplane, has come from France to compete against our American aviatresses, Miss Quimby and Miss Moisant A demonstration of military aviation was given the first day of the meet. An official aeroplane postal service was also maintained from the aerodrome to the outskirts of Brooklyn, so that letters or souvenir postals mailed on the grounds could be carried through the air almost immediately Various novel races and contests are also on the programme

A Wonderful Altitude Record.—In our last issue, we mentioned Beachy's new altitude record of 11,640 feet made at Chicago recently. This has since been exceeded by 2,000 feet by Garros in a Blériot monoplane On September 4th this daring French aviator ascended to a height of over 2½ miles (4,600 meters), or 12,954 feet. This startling performance would indicate that there is no limit to the height to which an aeroplane can soar Garros reached an elevation almost as high as Pike's Peak, in Colorado. It has always been supposed that the monoplane was more difficult to drive to such great elevations than the biplane, but such has been demonstrated to be untrue and the monoplane now holds the palm for height as well as for speed

A New Michelin Prize for War Aeroplanes.—Mons Michelin has just offered a new prize of $20,000 for bomb dropping by aeroplanes Mons Michelin, it will be remembered, offered a like amount for a flight of some 225 miles from Paris to the Puy de Dôme Mountain over three years ago, this prize being won last March—exactly three years to a day after it was offered—by Reneaux on his Maurice Farman biplane Mons. Michelin believes in the future of the aeroplane and thinks that large prizes should continually be offered with the idea of perfecting it still further The rules of the new prize have not yet been drawn up, but the idea is to give the prize to the aviator who is most successful in dropping the greatest number of projectiles nearest to a given spot marked on the ground.

New York's Aviation Meet.—Despite the fact that the big meets recently held at Chicago and Boston have both been financial failures, the Aero Club of New York, of which Honorable Timothy L. Woodruff is President, expects to hold an International Meet at its Nassau Boulevard Aerodrome from the 23rd to the 30th of this month. Arrangements have been made for several of the well known foreign aviators to compete at this meet. Mlle. Dutrieu, the aviatress, who recently won the "Femina cup" for a long distance flight of 2 hours and 23 minutes cross country, in which she covered 106 miles, expects to compete in her special Henry Farman biplane. The army aviators will also probably conduct manœuvres showing the use of the aeroplane in warfare, and there may also be made some experiments in the transportation of mail by aeroplane.

THE SEBASTIAN 16-INCH ENGINE LATHE
For Light Work.
The most easily manipulated lathe of its size on the market. Automatic Chuck, Carriage Stop and Compound Rest. Write for Catalog No. 14. The Lathe for the Machinist.

Caution to Purchasers of TOPS

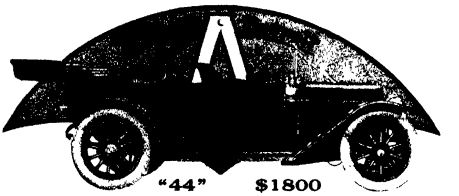
Pantasote

is a top material of unexplained high and uniform quality and a product made only by us. Many unscrupulous dealers misrepresent as PANTASOTE cheap inferior materials to increase their profits—at the purchaser's expense. The genuine carries above trade mark, which we will supersede like PANTASOTE.

Pantasote Company, 11 Broadway, New York

Engineering

Rare Metals in Canada.—It is reported that important deposits of platinum, iridium, palladium, rhodium and osmium have been discovered a few miles from Nelson, B C A well-defined dike bearing these metals is said to have been traced for several miles in the general direction of Forty-Nine Mile Creek and across the Kootenay River, and many claims have been staked.



Edward Whymper.—The death of Edward Whymper removes the nestor of mountain climbers, the man who led the way up the Matterhorn in 1865 and first showed the possibilities of the Canadian Rockies. Whymper's wonderful achievement in ascending Chimborazo (20,500 feet), has been surpassed by others, but he will always remain a pioneer of distinction. Some of his books passed through many editions, and are now regarded as classics. Whymper was well advanced in his seventy-second year He died at Chamounix, among the tall mountains and glaciers he loved so well

The Lotschberg Tunnel.—Although the great Lötschberg tunnel is now open, it will be two years before trains are crossing the Bernese Oberland The new tunnel is nine miles long; a little shorter than the St Gothard, and three miles shorter than the Simplon It was built largely through the enterprise of the business men of Bern, in order to divert to that city a share of the transalpine traffic, most of which is now monopolized by other Swiss cities which are more favorably situated with respect to the Simplon and the St Gothard Its construction occupied four years and five months, and was marked by two great catastrophes, an avalanche and a cave-in, each of which cost a number of lives

Irrigation of the Yangtse Valley.—A project is now under consideration to construct an elaborate irrigation system in the Yangtse valley—possibly the most costly undertaking of this kind in the history of engineering Its object is twofold, viz., to improve the agricultural conditions of the country, and—more especially—to prevent a recurrence of the terrible floods which have devastated the valley during the present year. Independently of this project, Charles Jameson, the American engineer sent to China by the Red Cross Society, accompanied by an engineer deputed by the Chinese government, is about to make a survey of the famine districts of Kiangsu and Anhui, which are subject to these recurring floods

Progress of the African Railways.—By next July there will be continuous railway communication between Cape Town and the town of Kambove, in the Congo, 270 miles north of the Rhodesian boundary, a total distance of over 2,400 miles The railway is already in operation as far as Elizabethville, 165 miles north of the Congo border From Kambove an extension has been surveyed to Bukama, 200 miles farther north, on a navigable tributary of the Congo In a few months a railway will be begun from Kambove westward 100 miles to Ruwe. This is destined ultimately to connect up with the line that is being pushed eastward from Benguela, on the Atlantic coast, and which now extends 230 miles into the interior

Relics of the French Panama Canal.—On September 5th bids were opened in Washington for the French "scrap" that so picturesquely and tragically strews the route of the Panama Canal. It includes abandoned locomotives, dump cars, tanks, barges, dredges, boilers, girders, sheet iron, parts of old machinery, and miscellaneous junk—the relics of De Lesseps's greatest and most disastrous undertaking Every one who has visited the Isthmus has brought away vivid recollections of these gaunt monuments, as well as of the incredible tales with which they have come to be embroidered It used to be related that the French settlement of Christophe, adjoining Colon, was built on a foundation of locomotives dumped by the shipload into the virgin swamp. The material is to be removed by the contractor at his own expense, the Panama Railroad charging $2.25 a ton for its transportation to the seaports. Three years will be allowed for the removal.

"44" $1800

7 PASSENGER FORE-DOOR TOURING CAR

YOU probably won't take the time to make the comparisons we hope you will, yet you must realize we could not afford to make statements about our cars, and not only that, but guarantee them for life, unless we were confident that Abbott-Detroit cars actually represented the value that we say they do.

When we say that in the Abbott-Detroit cars you get **exceptional value** for your money we mean it, and what is more, it will be plainly evident to you if you glance through these specifications and compare them with those of other cars selling at similar prices.

Where else will you find, **at this price,** as powerful a motor (advertised ratings do not count—look for the cylinder dimensions, they're important) a 4½ in x 5½ in four-cylinder, long stroke motor, with magneto and battery dual ignition system?

Likewise, where else will you find a better chassis—oil tempered springs—chrome nickel steel drive shafts—Timken roller and Schaefer annular bearings throughout—full floating type rear axle—a multiple disc clutch—extra large, strong *artillery wheels*—over-sized tires 36 in x 4 in.—universal demountable rims—wheel base 120 in? Everything of highest grade material and as well made as anyone can ask.

Big, roomy, ventilated fore-door bodies, painted, trimmed and upholstered with the greatest of care—24 painting operations alone, the latest electric lighting system complete with 180 ampere hour battery, black enamel lamps with nickel trimmings. Tungsten filaments

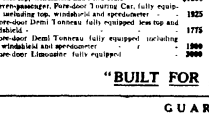
As for **reliability,** that quality which actual use alone can reveal at its true value, we point with pride to the wonderful performance of the Abbott-Detroit "Bull-Dog," which is daily adding mileage in its 100,000 mile tour of the United States

These are a few of the reasons why you owe it to yourself to see and ride in an Abbott-Detroit before you make up your mind which car to buy for 1912

SPECIFICATIONS AND PRICES

ABBOTT-DETROIT "44"

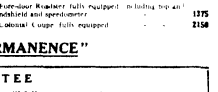
4½"x5½" long stroke Motor Dual Ignition System with Magneto.
Bullet Electric Headlights—combination oil and electric side and tail lights—180 ampere hour lighting battery—Tungsten lamps—body of lamps, black enamel with nickel-plated trimmings.
Two-pedal Control Clutch and Brake.
Horn and Tools.
Tires 36"x 4"
Universal Demountable Rims
Three-speed Transmission
Wheel base 120 inches.
Ventilated Fore-door bodies.
Seven-passenger Fore-door Touring Car, fully equipped less top, windshield and extra seats - $1800
Seven-passenger, Fore-door Touring Car, fully equipped including top, windshield and speedometer - 1925
Fore-door Demi Tonneau fully equipped less top and windshield - 1775
Fore-door Demi Tonneau fully equipped including top, windshield and speedometer - 1900
Fore-door Limousine fully equipped - 2000



ABBOTT-DETROIT "30"

4¼"x5½" Four cylinder Motor Dual Ignition System with Magneto.
Electric Headlights—combination oil and electric side and tail lamps—100 ampere hour lighting battery Tungsten Lamps
One pedal Clutch and Brake control—simple safe and sure.
Tires 34"x4½" Demountable Rims
Horn Tools
Three speed transmission
Wheel Base 110 inches
Ventilated Fore-door Bodies
Fore-door Touring Car fully equipped less top and windshield - $1350
Fore-door Touring Car fully equipped including top and windshield and speedometer - 1450
Fore-door Roadster, fully equipped less top and windshield - 1275
Fore-door Roadster fully equipped including top and windshield and speedometer - 1375
Colonial Coupe fully equipped - 2150

"BUILT FOR PERMANENCE"



GUARANTEE

This is to certify that the Abbott Motor Company will fully warrant and guarantee the Automobile covered by this certificate for its entire life, from the date of the original sale by the dealers This guarantee also includes all material and all equipment, with the exception of tires, magneto, lamps, etc., which are warranted by their respective makers, used in connection with construction of said automobile If any parts of this car break or prove defective from any cause whatsoever, and the customer shall forthwith communicate the fact to the Abbott Motor Company or one of its authorized dealers, giving the number of car and the name of the dealer from whom the car was purchased and the date of purchase, and it shall appear that such breakage was not in fact due to misuse, negligence, or accident, the Abbott Motor Company will furnish such new parts, either through its dealer or at the factory in Detroit, Michigan, free of charge to the owner This guarantee does not apply directly or indirectly to consequential damage of any nature whatsoever or to the replacement of tires, which are guaranteed by the makers thereof.

SCRIBNER'S MAGAZINE

The New Serial by one of the most popular of contemporary novelists begins

In the October Number

THE TURNSTILE

By A. E. W. MASON

Author of "The Four Feathers," "The Broken Road," etc. It opens with a dramatic earthquake in the Argentine.

General Grant's Letters to General Beale. Intimate letters of the great soldier to a life-time friend.

Cleveland's Administrations, by JAMES FORD RHODES. With reference to Civil Service Reform.

What Organized Charity Has Done for the Poor is the subject of JACOB A. RIIS'S *A Modern St. George.*

A brilliant article about the life and work of *Liszt,* by JAMES HUNEKER.

Hamburg and Its Harbor, by RALPH D. PAINE. Illustrated.

The conclusion of MRS. WHARTON'S *Ethan Frome.* One of the greatest stories this author has ever written.

The Greatest Horse Show. The International of London. By E. S. NADAL. Illustrations by FRED. PEGRAM.

Short Stories, etc., etc. Prospectus sent free upon request.

Special Offer: *For the next three months the publishers of SCRIBNER'S MAGAZINE offer extraordinary inducements to any one who secures a specified number of subscriptions to the Magazine. Agents wanted in every town. Write now for Booklet A, giving full particulars.*

Address SCRIBNER'S MAGAZINE, New York City.

Three Dollars a Year *Twenty-five Cents a Number*

The test of a magazine's merit

is that its readers tell their friends about it.

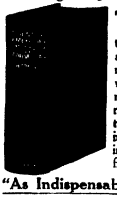
We recently asked our subscribers to send us the names of those whom they believed the Scientific American would interest, and we are gratified to find that so many of our subscribers believe that its merits will appeal to such a large number of their friends. Have you sent a list? If not,

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest. An accurate record of all names received in this manner will be kept, and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send.



Address all lists to Circulation Department, Scientific American, 361 Broadway, New York.

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty-Eighth Edition of "The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by **ALBERT A. HOPKINS,** Query Editor of the Scientific American

THIS is practically a *new book* and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters:

I Accidents and Emergencies.
II Agriculture
III Alloys and Amalgams.
IV. Art and Artists' Materials
V Beverages, Non-Alcoholic and Alcoholic
VI Cleaning, Bleaching, Renovating and Protecting
VII Cements, Glues, Pastes and Mucilages.
VIII. Coloring of Metals, Bronzing, etc.
IX. Dyeing
X. Electrometallurgy and Coating of Metals.
XI. Glass.
XII. Heat Treatment of Metals.
XIII. Household Formulas.
XIV. Ice Cream and Confectionery.
XV. Insecticides, Extermination of Vermin
XVI. Lapidary Art, Bone, Ivory, etc.
XVII Leather.
XVIII. Lubricants.
XIX. Paints, Varnishes, etc.
XX. Photography.
XXI. Preserving, Canning, Pickling, etc.
XXII. Rubber, Gutta-Percha and Celluloid
XXIII. Soaps and Candles.
XXIV. Soldering
XXV. Toilet Preparations, including Perfumery.
XXVI. Waterproofing and Fireproofing.
XXVII. Writing Material.
Appendix: Miscellaneous Formulas; Chemical Manipulation; Weights and Measures; Index.

ARTICLES *on* AVIATION
IMPORTANT AND INSTRUCTIVE

In the Scientific American Supplement we have published in the past few years papers by some of the more eminent physicists and engineers on flying machines. No book thus far published is so complete and so authoritative as these articles. The range of the articles is wide, covering as it does the theoretical side of aviation as well as those more practical aspects which deal with the construction of machines. The following is a partial list of the more important articles which have appeared in the Scientific American Supplement—see special note below.

Nos. 1816, 1817, 1818, 1819, 1820, 1821 and 1822. **The Practice and Theory of Aviation.** By Grover Cleveland Loening, A. M. This is the most compact paper on aeroplanes that has probably ever been published. Fourteen biplanes and monoplanes are described in detail, and illustrated with scale drawings, namely, the Farman, Cody, Curtiss, Wright, Voisin (old model), Voisin (new model), and Sommer biplanes, and the Antoinette, Santos-Dumont, Bleriot XI, Bleriot XII, Gnome, Pulsrie and Pfitzner monoplanes. The proper dimensioning of aeroplane surfaces, as deduced by famous experimenters from their tests, is also considered. The paper as a whole this series of newspapers constitutes an admirable text book.

No. 1713. **The Wright Aeroplane.** This is a thorough description of the old type of Wright biplane with the horizontal elevating rudder in the front of the machine. Excellent diagrams and photographic views accompany the paper.

No. 1756. **Louis Bleriot and His Aeroplanes.** Few people realize that Bleriot's successful monoplane is the result of ten years of daring and perilous experiment. In this paper will be found an instructive description of the evolution of the present successful Bleriot monoplane, illustrated with diagrams and photographs.

No. 1768. **The Farman Biplane.** A complete description of the Farman biplane, with detail drawings of the box tail and vertical rudder, the manner of working the four ailerons, hand and foot levers which control the machine, plan view and side elevation of the entire machine.

No. 1767. **The Santos-Dumont Monoplane.** An illustrated article describing the Demoiselle, the smallest and one of the fastest machines thus far made. Sketches accompany the article, showing the details of the construction and control.

No. 1582. **How to Make a Gliding Machine.** Full details and drawings which will enable anyone to make a glider for $15.00.

All these articles are profusely illustrated.

Special Note. We will mail (gratis) a list of many additional important papers, in the Supplement, treating of aeronautics. Ask for list "A."

Each number of the Supplement costs 10 cents, mailed, and you can order as many of them as you wish. A set of papers containing all the articles above mentioned will be mailed for $1.20.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The "Liberté" and the "Maine"

IT was inevitable that the destruction of the French battleship "Liberte" by the explosion of her magazines would revive in our minds the loss of the "Maine." Whatever the first cause, the results in each case were so identical, both in the loss of life and the complete destruction of the ship, as to make it certain that it was the letting loose of the enormous energy stored in the powder magazines that tore the two ships asunder and sent them swiftly to the bottom. At the present time it is hopeless to attempt to arrive at any satisfactory conclusion as to the ultimate cause of this horrible tragedy on the French ship. The dispatches contain the usual and inevitable mass of contradictory statements of eye witnesses and suggestions by experts. This, however, is certain, that among professional men in this country, both naval and military there is a grave suspicion that there is something wrong with the French smokeless powders. With the *similar accident* to the "Iena" fresh in mind, this suspicion is unavoidable. We notice that *one* apparently official dispatch states that all smokeless powder is being landed from certain ships, and that some of this powder was manufactured as far back as 1902—a period which antedates by several years the "Iena" disaster.

On the other hand, if it be true that a fire started in the paint room and ran from there to the coal bunkers and magazines, the question will at once be asked, "What in the world is a paint room doing down below the protective deck and in contiguity to the magazines?" On the ships of our navy the paint room is located immediately under the forecastle deck and up in the very eyes of the ship at the bow. And if a fire that proved difficult to control did break out below the protective deck, why, it will be asked, were not the magazines immediately flooded? Perhaps the answer is to be found in a cabled dispatch, which states that the commander of one of the French ships who recently flooded his magazines on the outbreak of a fire received a reprimand on the ground that his action was too precipitate.

It is pathetic that the gifted people who gave to the world that smokeless powder which has revolutionized naval construction should themselves so frequently be the victims of their own invention. If the "Liberte" disaster leads to a thorough overhauling and reorganization of the French navy (and the unending list of naval disasters strongly suggests that such an upheaval is necessary) the loss of the "Liberté," costly and tragic as it is, will not have happened in vain.

Section of Battleship for Big-gun Attack

THE tendency of target practice, as far as appropriations will allow, is in the direction of substituting the actual ship and solid armor for the time-honored canvas screen—and this for obvious reasons. Although the canvas target serves admirably its purpose of showing the accuracy of gun-fire, it gives no indication whatever of the punishing effect of such shots as get home upon the mark. Hitherto we have depended almost entirely for such information upon the results obtained by firing at armor plate, set up at a proving ground and attacked by a gun a few hundred feet in front of the target, whose projectiles have been delivered with reduced powder charges, giving a low velocity, corresponding to that at which the projectiles in an actual engagement would reach the ship when fired at long ranges. A disadvantage of most proving-ground trials is that the projectiles strike the plate normally to its face, and therefore under the best conditions for penetration, whereas in an engagement, carried out at ranges of from eight thousand to twelve thousand yards, the shells will be descending at an angle of from seven to ten or more degrees.

Our ordnance officers have always recognised these facts, and it is only recently that a liberal policy and more generous appropriations have enabled them to test the resistance of the armor and the ship under conditions at least approximating those of the future sea fight. Our readers will have in mind the "Katahdin" experiments, when heavy armor plate which had been erected on this obsolete vessel was attacked by a 12-inch gun, at ranges of 8,000 yards and up. Even more valuable in the information gained was the famous target practice against the "San Marcos," formerly the "Texas." Here the test was of the resisting power, not only of the armor, but of the whole ship itself, to modern gun attack.

It is necessary to take but one step further to give the navy absolute information on this subject, and this would be to sacrifice one of our modern ships, carrying the latest armor, backed up by the most approved methods of interior reinforcement and subdivision, by mooring her in Chesapeake Bay and permitting one of our latest ships to subject her to a bombardment similar to that which tore the "San Marcos" to pieces and quickly sent her to the bottom. But not even the information of priceless value which could be thus secured would warrant so costly an experiment.

There is, however, a cheaper way to secure the desired information. That is by building a floating structure of limited displacement, representing an exact section of a modern battleship, whose behavior under gun attack would be sufficiently similar to that of the ship itself to afford our naval constructors and ordnance officers a large amount of greatly needed information. Now, it is exceedingly gratifying to learn that there has been constructed at the Norfolk Navy Yard an experimental caisson which represents a battleship on one side and a cruiser on the other.

The caisson is being subjected to attack by guns, big and little, at ranges corresponding to those which may obtain in the various stages of a hard-fought naval engagement. In the present case, there is no such wholesale bombardment as marked the spectacular destruction of the "San Marcos." That sham battle was carried on mainly as a test of the accuracy of our modern system of correcting the range by spotting the fall of the shots. The tearing of the old ship to pieces was a foregone conclusion. Outside of the fact that it lent a touch of realism for the officers and men, and provided no end of stimulating "copy" for the press of the country, the lessons of the bombardment were necessarily, because of the great age of the ship, of limited value.

In the attacks on the caisson, however, we venture to think that after every single successful hit, the structure will be visited by officers of the line and staff, who will take careful count by photograph, and sketch and note book, of every detail of the damage inflicted. Each hit will have its own story to tell; and thus by alternate attack and inspection, round by round, our navy will lay in a store of practical information, the like of which, we venture to say, has never before been gathered by any navy in the world.

Foreign Students at German Universities

THE fame of the German universities is such as to render it quite unnecessary to extol their praise or to recite at length the many virtues for which they are so deservedly held in universal esteem. A question which invites discussion, however, is the influence, both upon Germany and upon the other countries, which the steady migration of students from abroad to the German seats of learning, and their subsequent return to their home countries, must exert both on Germany and upon the world at large. There is something slightly humiliating in the thought that we—and we do not stand alone in this matter—must needs send some of our best students to Germany, so that they may there receive what our universities seem to be unable to give them. While we would not for a moment entertain the desire or hope that this flow of young American manhood to Germany should ever diminish, yet we may very well harbor the wish that the causes for it may in time change, and that there may be an equal inducement in days to come for German students to visit our schools. There can be little doubt that a certain kind of academic work receives more attention and appreciation in Europe than it does with us, and possibly the causes for this are so deeply ingrained in the American national character that they can never be removed. In that case, the future to which we must look forward is that in time our universities may develop their own special points of excellence, for which they will be sought out by students from abroad. To some extent this is, no doubt, the case even now. Those who have themselves imbibed a little of the spirit of the old-world devotion to scientific investigation and to the study of art and literature, will, we think, hardly be quite satisfied with such a programme. Only the future can show just what course events will take.

Much more might be said on this side of the question, the influence of foreign studies upon our own country. There is, however, another aspect to the situation, which has recently been discussed in the pages of the *Zeitschrift für angewandte Chemie* by J. Bronn, namely, the effect which the extensive visitation of German universities by foreign students must have upon Germany itself. There are those, among the Germans, who feel some entirely justifiable jealousy in seeing the citizens of other countries, sometimes not particularly friendly to Germany, reaping of the harvest sown specifically for Germans by Germans. That such feelings should be voiced is perfectly natural, but it is also quite obvious that they are framed from a rather narrow point of view, which is not only somewhat repellent, owing to its selfish ring, but in view of the failure to take into account certain factors, is probably entirely fallacious. And these factors assuredly far more than compensate for any losses which Germany may suffer in the way indicated. Mr. Bronn considers the effect of the attendance of foreigners at German universities, first upon the state, secondly upon German industries as a whole, and thirdly upon the chemical industry in particular.

As regards the first point he observes that Germany as a State does not enjoy very great popularity among other nations, and he points out that this fact cannot be viewed with indifference by a country which, like Germany, carries on extensive export trade. The young student arrives in Germany with a good stock of prejudice, and instead of mixing with the natives, as would be best for all concerned, prefers to keep aloof and frequent only the company of his own countrymen. It is usually not until after two or three years' sojourn that he begins to become acclimatised, and from this point on he learns to appreciate the good points of German character and German customs. He returns to his home country with his views radically changed, and takes every opportunity, if only in a spirit of contradiction, to sing the praises of Germany. The value to Germany of this kind of missionary work can not be estimated too highly.

Passing on to the discussion of the second point, namely, the effect upon Germany industry of an increase in the enrollment of foreigners at the German universities, Mr. Bronn remarks that such effect must be slight, for foreign students, practically without exception, return to their home country after the completion of their studies. There is, therefore, no question of competition by the stranger with the native fog industrial positions.

On the other hand, the market for German products is most favorably influenced, for the man who has been trained in Germany will invariably give his first thought to German wares when considering the purchase of goods or machinery which cannot be procured in his own country.

Finally, as to the third point, the effect of foreign students upon the chemical industry of Germany, the same remark applies with regard to German exports in this field, as was made above with reference to German exports generally. The fear may be expressed that the graduate from a German university, upon settling down in his home country, will make use of the knowledge imbibed from German sources to place upon the market by home production the wares which until then had been imported from Germany. But as a matter of fact, every chemist knows that the mere university training, without experience in actual manufacture, is quite insufficient to enable a man to successfully establish a manufacturing installation on his own initiative, to say nothing of the very serious questions of capital, raw material, etc., which place severe obstacles in the path.

Fig. 1.—This reads 83,600 cubic feet.

The Meter

That Inexorable Mechanical Accountant of the Gas Company

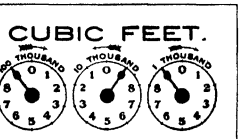

Fig. 2.—This reads 88,900 cubic feet.

NINE-TENTHS of the distrust in which the gas meter is almost universally held is directly traceable to its obscure location in the dark, unpleasant surroundings of the cellar. We feel sure that the man who is loudest in his denunciation of this "instrument of extortion" makes no daily or even weekly trips down his cellar stairs for the purpose of verifying the totals footed up by the gas meter. If he did we are confident that much of his distrust would give way to respect. This same man may be most scrupulous about all his other accounts and would think it the height of absurdity to jot down his expenditures but once a month, with no memoranda to assist him in recalling the various items. Yet with ridiculous inconsistency he is ready to denounce any enlargement of the gas bill, forgetting that a whist party and a few friends to dinner or a succession of cloudy afternoons may have increased his gas-light hours—hours that are by no means overlooked by the mechanical accountant of the gas company.

However, we are not writing a defense of the gas meter. It is by no means a perfect instrument, hence the necessity of checking its records periodically. Unfortunately not one man in a thousand knows how to read a meter, yet there is no great mystery about it. Directions are published either on the back of the gas bill or on cards issued by the gas company, which may be had for the asking.

The meter is usually provided with three or four dials, each graduated in ten divisions. A small dial marked "Two feet" may be ignored for the present, as it is used only for testing purposes. The dial to the right is marked "1 thousand" and each of the divisions stands for 100 cubic feet, the entire circuit of the dial representing one thousand feet. On the next dial, marked "10 thousand," the hand moves in the opposite direction and each division stands for a thousand feet. In the same way each division of the dial marked "100 thousand" stands for ten thousand feet. Fig. 1 shows a simple example which will illustrate the method of reading. From this reading, the reading of the previous month is subtracted to show the amount of gas used in the interim. It should be noted that when a hand lies between two figures, the lesser number is read.

It is sometimes puzzling to know whether a hand lies on a figure or not, and this can be determined only by referring back to the dial on the right. For instance, if all three hands pointed to 9, we might carelessly put down the reading 99,900, which would be just 11,000 cubic feet out of the way. The true reading is 88,900, as a moment's consideration will show. The fact is made clearer by referring to the hands of a clock. When the hour hand of the clock points to X, and the minute hand to XI, we read not 10.55, but 9.55, because the minute hand shows us that the hour hand has not yet reached X. And so with the gas meter hands; the hand of the first dial shows that the hand of the second dial has not quite reached 9, although it may appear to be covering that number, while the hand of the second dial shows that the hand of the third one has not yet reached 9. It happens not infrequently that a meter inspector will make a mistake in such a reading, which may boost the gas bill considerably. Of course, the fault will right itself eventually, for at the end of the next month, there will be a larger subtrahend to deduct from the meter reading, and a correspondingly smaller bill. Sometimes an inspector, knowing about how much gas is used, will guess at the reading, if he finds it impossible or inconvenient to reach the meter when on his rounds, making his estimate low so as to be on the safe side. Then when he does make a *bona fide* reading, the gas bill will show a sudden rise, making up for the accumulated deficiencies of the inspector's low estimates.

In 1907, the Public Service Commission of the First District of New York took over the power and duties of State inspector of gas meters in Greater New York, since which time the citizens of this metropolis have been protected by all manner of safeguards against the possibility of fraud. All meters are carefully tested by the Commission and must bear its seal before being placed in a building. This seal indicates that the meter, when tested, was correct or not more than 2 per cent slow. A slow meter is one that does not register the full amount of gas passing through it, while a fast meter makes the consumer pay for more gas than he uses. No meter is allowed to be placed on a consumer's premises that runs at all fast, but if on a complaint a meter is not more than 2 per cent fast it is passed as correct. For the absurdly small fee of 50 cents (this applies to the smaller meters, for the larger meters from 20 to 300 lights and upward the charge is from 75 cents to $2.00), any one in New York can have his meter tested, and if the meter is found to be running more than 2 per cent fast, not only is the fee refunded and charged to the gas company but the latter must make a settlement with the consumer for the unconsumed gas he has been paying for. From July, 1907, to July, 1911, 19,970 gas meters were tested on complaint, 45.8 per cent of these were found to be correct or within 2 per cent fast or slow, 10.3 per cent were found to be slow or running to the disadvantage of the gas company while 43.9 per cent were fast. The variation of the meters averaged a very small figure however, showing that the work of the meter itself was on the whole very creditable.

When a complaint is made to the Commission, a complaint inspector visits the consumer and makes a thorough inspection of his premises, searching for leaks. Occasionally a leak will be discovered near an open window or close to a chimney flue, where the draught will carry off the gas into the open, letting it escape undetected. Sometimes a jet is left burning in an attic or in some unused room such as an amateur photographer's dark room, and the tenant comes back after a month or two of vacation to find a gas bill awaiting him. Not infrequently in apartment houses the meter is found to be connected with the wrong apartment and one man is then paying the other man's bills. Troubles of this sort account for the running of the gas meter when no gas is used. As a matter of fact, the meter can register nothing if no gas passes through it. When satisfied that there is no trouble with the pipes, the meter inspector seals and tags the meter and has it removed to the testing station.

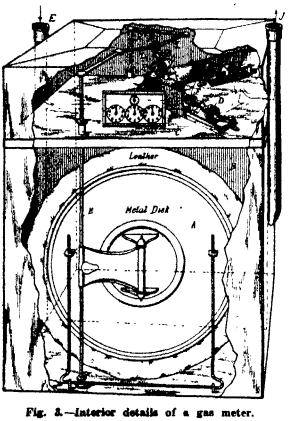

Fig. 3.—Interior details of a gas meter.

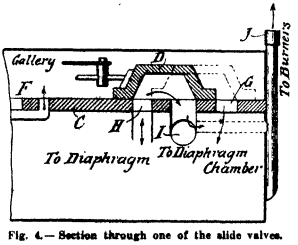

Fig. 4.—Section through one of the slide valves.

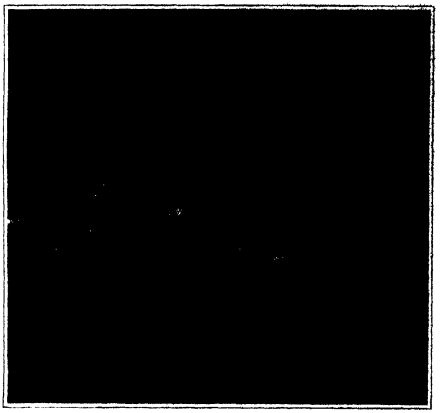
The manner of testing the meter is simple. A measured quantity of air is passed through the meter, and the two foot testing dial of the meter is noted, to see whether it registers this amount correctly. The prover in which the air or gas is contained is built just like a gasometer, consisting of a cylinder, with open bottom which telescopes within another cylinder filled with water to form a seal between the two. The inner cylinder is provided with a port which may be opened to admit air as it is raised. This port is then closed, sealing the air within as in a diving bell. The meter is now connected with the cylinder, and after care has been taken to make all the joints tight the air is allowed to pass out through the meter. When two cubic feet of air have passed through, as indicated by the small dial, an indicator on the prover should show that two cubic feet of air have actually issued from the cylinder. If over two per cent plus or minus is indicated, the meter is rejected and must go to the repair shop. Usually three readings are taken and the average of the three determines the condition of the meter, this precaution being observed so as to do away with the personal equation which might be a factor of serious importance if but a single reading were used.

If we follow the meter to the repair shop, we shall have a chance to investigate its interior construction and learn something of the ailments to which it is subject.

The drawing in Fig. 3 shows us how a meter would look if the front wall of the tin casing were torn off. Probably the first object to catch the eye would be the large circular bellows that occupies the lower part of the meter at *A*. There is another bellows of the same size and shape on the opposite side of the central vertical partition *B*. These bellows or "diaphragms," to use the technical name, consist of a ring of metal soldered to the partition *B* and connected by a strip of flexible leather to a metal disk. The diaphragms are the lungs of the

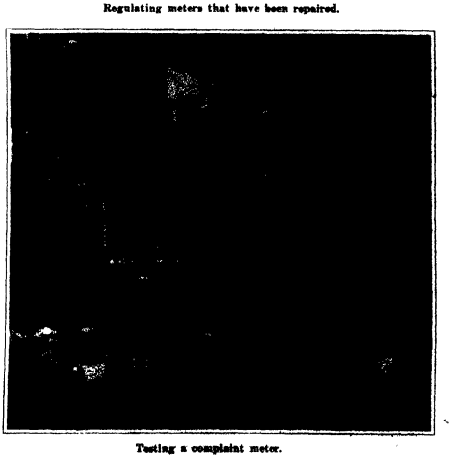
Reconstructing condemned meters.

THE METER



meter which inhale and exhale measured quantities of gas, while a counting mechanism is actuated by the heaving lungs, and indicates the count on the dials.

The counting mechanism is situated in the upper chamber or "gallery" formed by the horizontal partition C and here also are the slide valves D that admit the gas to the diaphragms. A somewhat diagrammatic section through one of these valves is shown in Fig. 4. Gas enters the meter through the tube E and flows into the valve chamber through the port F. The valve port G leads to one of the diaphragm compartments, while the port H leads to the interior of the diaphragm in that compartment. The outlet port is shown at I, and it leads through pipe J to the burners in the house. The valve D is shaped to provide communication between the outlet port I and one or other of the ports G and H at all times so that there is no interruption in the flow of gas out of the meter. With the valve in the position shown by full lines in Fig. 4, the gas is slowly filling the diaphragm chamber and flattening the diaphragm which in turn is exhaling the gas it contains by way of the ports H and I. When the valve moves to the position shown by dotted lines, gas enters the diaphragms through port H and, as the diaphragm expands, under the pressure of the mains, it causes a proportionate amount of gas to flow out of the chamber through ports G and I to the outlet J. As there are two sets of diaphragms and valves operating in alternation, there is no appreciable variation in the pressure of the outflowing gas.



Each diaphragm is connected to a vertical rock shaft provided with a crank arm, and connected by a link L to a sleeve M adjustable on an arm N projecting from the valve shaft O. The combined motions of the rock shafts as they are oscillated by the inhaling and exhaling diaphragms, cause the valve shaft to rotate, and by means of connecting rods P to operate the valves. By means of a worm and gear R, the counting mechanism is operated. The dog S serves to prevent the mechanism from running backward, and it is the action of the arm N striking this dog that produces the clicking noise which may plainly be heard when gas is flowing through the meter. Adjustment of the meter is provided by sliding the sleeve M in or out upon the crank arm N.

It is not very reassuring to the consumer to know that the majority of troubles that affect the gas meter tend to make it run fast rather than slow. As the parts become loose with wear there is a tendency for them to run faster, and as the leather bellows are saturated with moisture condensed from the gas, they shrink and deliver less gas at each aspiration. Sometimes so much water collects in the meter case that it seriously hinders the opening and closing of the bellows and they operate only when partially filled. Here again the consumer loses.

There is another difficulty which should be considered, but which, however, can be overcome by a very simple device. Normally the pressure used in New York is "15 to 25 tenths" to use the trade expression, which is equivalent to about one-half to one pound water pressure, U or siphon gage measurement. If for instance, the pressure should be increased to, say, 40 tenths, 50 per cent more gas would be consumed at the burner and although there would be an increase in light, it would not be sufficient to compensate for the increase in the gas bill. On the other hand, the meter would not register the full amount of gas passing. There would be a loss of about 2 per cent which the company would have to stand for. To obviate this trouble, a governor is provided, which may be placed upon the service pipe before it enters the meter. This will hold the pressure down to the normal limit. There was a period, from 1907 to 1909, when the pressure in New York was confined by law between the limits of 15 and 25 tenths. This limitation was finally withdrawn on the representation of the gas companies who claimed that owing to friction when conducting gas over a long range, it is necessary to use a high initial pressure in order to maintain sufficient pressure at the end of the line. Still another factor to be considered is the elevation of the burner. The pressure at the crest of a hill is more than that in the valley below; on the ground floor of a skyscraper it would be much less than at the top. There is a difference of one-tenth pressure for every 14 feet of elevation, so that at the top of a 700-foot structure like the Metropolitan tower, twice as much gas would flow through a five-foot burner as at the street level. However, it is only in naked gas flames that there is a loss due to high pressure. Incandescent mantle lamps are self-governing and will consume only a fixed quantity of gas, while if the gas is used for cooking purposes there is no loss; for a rise in pressure will result in a corresponding rise in temperature.

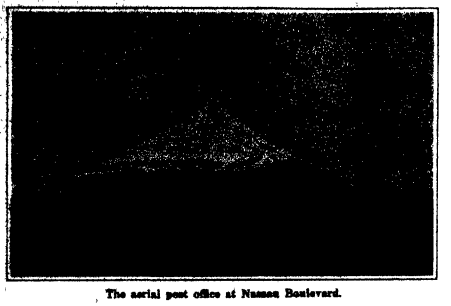
THE METER

The Burning of the German Military Dirigible "M III"

By Carl Dienstbach

THE crack dirigible of the Germany army, the semi-rigid "M III.," was partially destroyed by fire just before the end of the "Kaisermanoeuvers," in which it had rendered valuable services on the "red" side.

The circumstances of this accident are interesting and instructive. The "M III." was of the Gross-Basenach German semi-rigid system, which differs from the original French semi-rigid Lebaudy system in separating the gas bag from the stiffening frame, causing the latter part of the suspension, and dividing it into three separate sections better to withstand shocks in landing and facilitate dismantling. The envelope is similar to that of the Parseval system, having two ballonets fore and aft, with a distributing valve for the air between, to assist the vertical steering, which is done principally by shifting water with a pump between two tanks at the extremities of the combined stiffening frames. A seemingly slight, but as the accident has shown essential, defect was traced to the position of the blower for the ballonets. It is not carried in the car, but far above it, next to the frames, and driven by rope transmission to reduce the drag in the air of a long hose connection between car and envelope.



The "M III." displaced 240,000 cubic feet, had a length of 300 and a beam of 38 feet. The car was 40 feet long, and the distance between the bottom of the car and the top of the envelope stood 67 feet. The horse-power was 300, furnished by four Koerting motors, driving two propellers. The "M III." was equipped with wireless telegraph apparatus, and armed with apparatus for discharging explosives. In the maneuvers the whole crew of seven was furnished with rifles, kept in a special rack. Five of the crew were required to handle the ship, and two were observers. All but the engineers were army officers.

In this year's army maneuvers in Mecklenburg, Uckermark, and Pommerania, from September 7th to 14th, the "M III" had successfully performed all its allotted tasks, and, after ascending from Demming, Pommerania, in the morning of September 13th, was cruising in steady, certain flight over the villages of Golchen and Clempenow, when suddenly the rope transmission to the blower snapped. The gas bag began to lose its shape, and repairing in the air being not feasible on account of the blower's position, a landing became imperative. The dirigible was then drifting with useless motors toward a broad stretch of meadow on both banks of the Tollense River, a tributary of the Peene. From the air, in consequence of a well-known optical illusion, this meadow was apparently perfectly level and an excellent landing place. The pilot was evidently not an experienced airman, for he failed to recognize that the land formed a shallow valley, into and across which a lively "ground breese" was sweeping.

The descent, gentle at first, became suddenly very rapid when the airship caught in the descending current. The shock on striking the ground was quite violent. The ponderous envelope and framing continued to come down after the car had struck; fortunately, the wind carried it to the side of the car. From previous experiences with spherical balloons and investigations, it appears practically certain that the tremendous momentum of the heavy flabby mass of rubberised cloth of the gas bag and air ballonets, weighted with the framing and, in consequence of the quick descent, carrying a charge of atmospheric electricity, produced minute electric sparks through friction during this violent commotion; for the weather was very dry and hot. The shock at striking the ground also must have started leaks in the valves. The concussion instantly produced a certain quantity of explosive mixture of air and gas (normally the gas bag of a dirigible, unlike the envelope of a spherical, is hermetically sealed against the atmosphere by its safety valves), for there was a dull heavy report immediately after the envelope struck the ground, which shook the windows in the village of Gross below, and a column of flame shot up, which quickly consumed the gas bag with the planes, the framing, and the belly blower.

Fortunately, the crew could easily escape by jumping from the car on the opposite side, and the car with the motors and propellers was little harmed.

The accident is very instructive in showing how greatly the safety of a dirigible depends on the airmanship of the pilot, and that the facility to deflate and collapse, in place of being a guarantee of security, may, on the contrary, become a source of danger.

The aerial post office at Nassau Boulevard.

A card transmitted by aerial post.

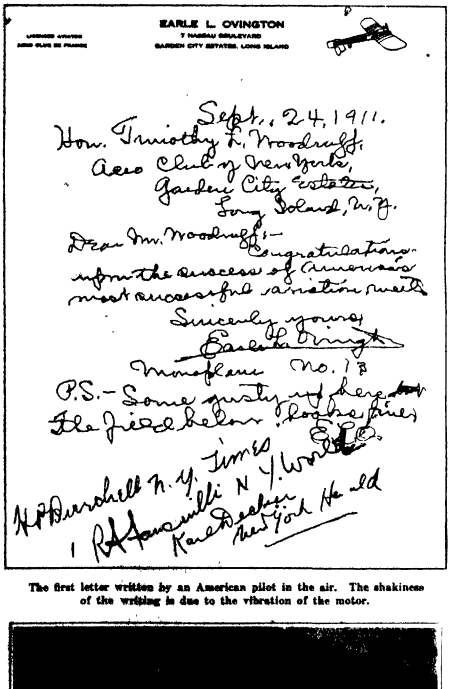
Carrying Mail by Aeroplane

The First Experiments in this Country at the International Aviation Meet

ALTHOUGH the primal practical use of the aeroplane, as conceived by the Wright brothers, was for purposes of war, perhaps the regular carrying of mail will be the first actual use to which it will be put by our government.

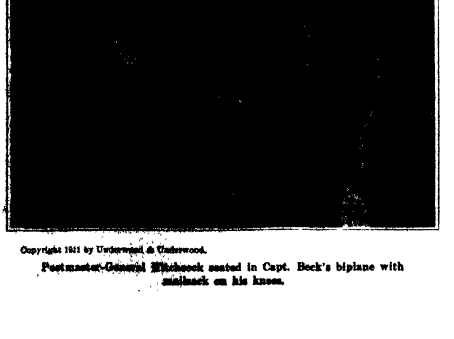
The first experiments in carrying mail were made by the British government in India last winter, when mail was carried from the Allahabad exposition grounds to a point several miles distant. Early in the present month, an aerial postal service was maintained for about a week between Hendon (near London) and Windsor Castle. This is a distance of some twenty miles. The mail was carried with more or less regularity by three machines—two biplanes and a monoplane, piloted by Driver, Hubert, and Gregwell. The last named made the opening flight on his Blériot racer in a 25-mile wind, carrying letters sent by the King, Queen, and Postmaster-General to the Mikado and all the crowned heads of Europe.

On the opening day, 11,000 to 13,000 letters were carried, and all told, over 100,000 letters and postals were started on their way by the air route. It was in the maintaining of this mail service that Lieut. Cammell fell to his death. Strong winds delayed it on some of the days, but on the whole the service was maintained with commendable regularity.



When it was decided to hold an aviation meet at the Nassau Boulevard Aerodrome, one of the first features determined upon was an aerial postal service to Brooklyn. Postmaster-General Hitchcock authorized this service, and so interested was he that he personally carried the mail on the fourth day of the meet.

About a score of letter boxes were placed around at different parts of the grounds. These were labeled "Aerial U. S. Mail," and two collections were made each afternoon. The mail was taken to a special tent, where it was stamped and assorted and placed in small bags containing from ten to fifteen or twenty pounds. Instead of carrying the mail to the outskirts of Brooklyn, it was taken a few miles farther away from New York to Mineola and dropped in a field at the feet of the postmaster, who was on hand to receive it at the appointed hour.



Starting on Saturday, September 23rd, Earle L. Ovington, in his Blériot monoplane, made regular deliveries twice a day. On Sunday, the big day of the meet, there were 6,165 post-cards, 731 letters, and 55 pieces of printed matter to be transported. One bag weighing 14 pounds was carried by Ovington, while another, which weighed about 20 pounds, was given to Capt. Beck to be taken in his Curtiss biplane. Capt. Beck had trouble with his motor, however, and the heavy bag was carried by Tom Sopwith in his Wright. On Tuesday when Postmaster-General Hitchcock himself carried the mail the pouch which he dropped overboard at Mineola contained 162 letters and 1,400 postal cards while the one carried by Ovington who showed him the way, had 300 letters and 2,200 postal cards, besides 78 other pieces of printed matter.

But one day during the meet was the mail service interrupted, which speaks well for the aeroplane as a regular mail carrier. Several days there was a strong wind, and two days it rained.

A demonstration of skillful airmanship was made by Mr. Ovington when he wrote a letter with a widely advertised fountain pen while aloft in his Blériot monoplane. Before ascending Ovington gave a blank sheet of paper to representatives of three New York newspapers, who wrote their names upon it so that they could identify it after the exploit and testify to the genuineness of the document. This letter is reproduced herewith, together with a postal card which was sent by aerial post. Ovington was able to write but once in a while, when the machine tipped sidewise, or tended to dive his pen would slip slightly. The vibration of the motor caused the irregular writing shown in our reproduction of his letter, but the fact that he could write at all while flying a fast monoplane, shows the control which he had over his machine. He operated his warping mechanism and horizontal tail rudder with his left hand while writing.

The first letter written by an American pilot in the air. The shakiness of the writing is due to the vibration of the motor.

Copyright 1911 by Underwood & Underwood.

Postmaster-General Hitchcock seated in Capt. Beck's biplane with mailsack on his knee.

It is to be hoped that the successful demonstration of mail-carrying that was given at the recent meet will cause the Postmaster-General further to consider the aeroplane for this use. It is quite possible to dispatch mail from New York to Boston or to Philadelphia and send it through without a stop. A gain of one or two hours could be made in the first instance and the establishment of the service between New York and Philadelphia would make it possible to send a letter in the morning at the opening of the business day and receive a reply early in the afternoon, whereupon a second letter could be forwarded and received before nightfall.

It is said arrangements are about to be made by transatlantic steamship companies for the special delivery of certain classes of foreign mail from the deck of the steamer as it approaches the coast to some station or locality in New York city by aeroplanes carried on the ship. By this means much quicker delivery could be effected.

Aeroplanes may yet be used for carrying messages or light life saving lines ashore from a stranded steamer when the distance from shore is beyond the range of the usual cannon.

The Diesel Engine

The Development of a Remarkable Motor

By Hayner H. Gordon

ANY one who has seen a large triple expansion marine engine in operation has been impressed with the mechanical beauty of the machine Light and powerful yet easy running, with complicated structure yet mechanically simple, it appears as though this type of engine had at last reached perfection And yet to-day it stands ready to be replaced by a new type of engine and motive power, a motive power that even a few years ago was largely ridiculed for its unreliability The gas engine is conquering the land, has conquered the air, and is now beginning to claim the sea for its own

All internal combustion engines are divisible into two general classes those in which combustion takes place at constant volume, and those in which combustion takes place at constant pressure, the first being known as the Otto type and the second as the Brayton or Diesel type

In order to make the difference between these two types clearer, it will be well to follow the cycle of operations in each case In the Otto four-cycle engine, the piston on the first stroke down draws in the combustible mixture. The up stroke then takes place, compressing the charge to a pressure limited by the ignition temperature of the charge used This is usually from 60 to 120 pounds per square inch, at the top of this stroke the charge is ignited, and the piston is driven down by the pressure generated by the explosion of the charge The fourth stroke then follows, the piston rising and the exhaust products passing out through the opened exhaust valve

In the Diesel cycle the first stroke of the piston draws pure air into the cylinder, the piston then rises, compressing the air to a pressure of 500 or 600 pounds to the square inch, and thereby raising its temperature to about 500 deg C This high pressure is obtained by having very small clearance At the top of the compression stroke an oil valve in the cylinder head is opened, and oil is forced into the cylinder in the form of a fine spray This is at once ignited from the highly heated air, and continues to burn until the oil is cut off at about one-quarter to one-third of the down stroke of the piston Expansion follows for the rest of the stroke, and the fourth stroke then takes place as in the Otto cycle

In the two-cycle engines of either class the piston uncovers ports at the end of its downward travel, the exhaust products passing out through one set of ports while the new charge is blown into the cylinder under slight pressure through the other ports The charge of course consists of combustible mixture in the Otto engine, and air in the Diesel engine Compression and working stroke then follow as in the case of the four-cycle engine

Three points of superiority of the Diesel engine over the Otto engine will at once be noted The first of these is the fact that there is no igniter present in the Diesel engine, and that therefore no ignition trouble can take place Also there will be no trouble from pre-ignition, for there is no fuel in the cylinder during the up stroke of the piston

The second point is that there is no carburetion or mixture troubles In an engine of the Otto type there is always a varying amount of exhaust products present in the mixture at various speeds which necessitates close regulation of the fuel supply In the Diesel engine the speed and power of the engine are entirely controlled by regulating the point in the working stroke at which the fuel is cut off The last point in favor of the Diesel engine is the fact that the change in pressure is not violent as is the case in the Otto engine, but gradually increases during the compression stroke, reaching the maximum at the end of the stroke and then remaining approximately constant until the fuel cut-off takes place

The cylinders of the Diesel engine are of small bore with a long stroke The pistons have to be well fitted in order to retain the high compression Sometimes as many as ten piston rings are used for this purpose

The fuels which may be used in the Diesel engine range from the lightest hydrocarbons to the heaviest crude oils As the fuel must be entirely atomized upon entrance to the cylinder, we find a great many different types of valves for the different grades of oil The valves are divisible, however into two general classes Those which make use of a fuel pump to force the fuel into the cylinder, and those which use compressed air to blow it in Valves of the first type comprise a small passage through the cylinder head with a needle valve to adjust the nozzle or spray and which opens into the cylinder Fuel is pumped to this spray valve by a small single acting plunger pump, at a pressure of 750 pounds per square inch, the length of stroke of the pump plunger being generally made adjustable, in order to time the admission of the fuel to the work of the engine.

The compressed air fuel admission valve is more largely used than the type just described. This valve usually consists of a hollow plug fitting in the cylinder head of the engine, and containing an inwardly opening check valve in the inner end. The hole in the center of this plug receives the charge of oil under a few pounds pressure, during the compression stroke of the engine, and then high pressure air at 750 pounds is admitted to the chambered plug, and the oil blown into the cylinder of the engine in the form of a fine

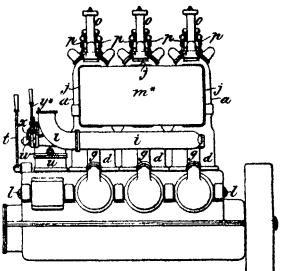


Fig. 1.—Reversing gear dependent upon changing position of cams relatively to the crank shaft.

spray. A valve of this type of course necessitates the use of a separate air compressor, but this is generally needed any way in order to furnish compressed air for starting the engine In order to start the engine by compressed air, there is an auxiliary starting air inlet valve, which is operated from a cam on the camshaft to admit the high pressure air on a portion of the working stroke of the engine, thereby running it as an ordinary air engine As soon as the engine picks up speed, the air valves are thrown out of operation by lifting the rockers off the cams or other equivalent method, and the engine picks up its regular cycle.

In addition to being equipped with self starting apparatus, the Diesel motor must also be made reversible, when used for marine purposes In the case of low

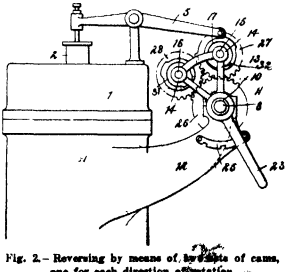

Fig. 2.—Reversing by means of, two sets of cams, one for each direction of rotation.

power and small engines, it is possible to use either a reverse clutch or a reversible propeller, but such practice is impossible in engines of a thousand horsepower or over

There are two methods employed in practice for reversing marine motors. The first is to change the angular position of the cams with respect to the crank shaft, and each other.

Fig 1 shows a small Diesel marine engine employing this method of reversing This engine possesses very unusual features in regard to the starting It is of the two-cycle type, with exhaust ports controlled by the piston, and possesses an air compressing cylinder for each engine cylinder. To start, compressed air from the air tanks is admitted to the pump cylinders, which act to drive the engine until it picks up its cycle. This engine employs two separate cam shafts, one operating the oil valves and the other driving the pumps. The adjustment of the shaft is made by means of sliding spiral gears which drive the cam shafts. These sliding spiral gears are controlled by the longer lever on the left hand end of the engine. The short lever controls the starting air.

The other method is to use two sets of cams, one set being used for each direction of rotation. These cams are sometimes placed on the same cam shaft, which is made longitudinally adjustable under the lifters. A modification makes use of two cam shafts, one for ahead and the other for astern. These shafts may be swung in position under the valve lifters. Such an arrangement is shown in Fig. 2

The reversing mechanism for the two-cycle engines is not quite so complicated as that for the four-cycle, the only valve mechanism necessary being that for the starting and fuel valves.

Probably the one feature of the Diesel motor which is causing its introduction into the marine field more than anything else, is its efficiency. Tests have been made on large engines of this type which show the almost remarkable figures of 0.38 pound of fuel used per brake horse-power hour. This is for crude oil. The marine engines of this type now in use average from 0.40 to 0.44 pound of fuel per brake horse-power hour while running under full load. When we compare these figures with those of the best triple expansion marine engines, which burn 1.46 pounds of coal per brake horse-power hour, we at once see the great advantage of the Diesel engine. In round figures, the Diesel engine will drive a ship just as fast and just as far on 100 tons of fuel, as a steam engine would on 350 tons of coal Moreover, the liquid fuel may be stored in tanks placed in the double bottom of the ship; thereby giving space formerly occupied by the boilers and coal bunkers, over to passenger and cargo space The earning power of the ship is thereby increased; the engine room space needed for an oil engine is just about the same as the engine room needed for the steam engine equipment.

The accessories needed for the Diesel engine require about the same space as the condenser and pumps of the steam engine

The construction of the marine oil engine seems to follow along the standard lines laid down by steam engine practice; all the large oil engines so far constructed have a short piston and use flat guides, and a cross head with the ordinary open construction It has been stated that it is poor practice to use the trunk piston, on account of the slight longitudinal movement of the crank shaft as the thrust bearings wear With flat guides this slight play would make no difference, and the open construction also renders inspection easier.

The air pump for obtaining air for starting, and for fuel injection purposes, is generally obtained from a three-stage air compressor, which is driven from the cross heads of the three cylinders, air being cooled between the compressor stages The circulation pumps are also driven from the main engine; but an auxiliary air compressor and auxiliary circulation pumps driven by smaller oil engines are provided for breakdown purposes. The bilge and fire pumps are either electrically driven, or driven by a separate engine, and electric current for light and power purposes is provided by direct-coupled generators driven by oil engines.

The oil engines in use at the present time—and building—comprise both two and four-cycle single and double acting Each type has many good features of its own and it is almost too early to state which is the better; the construction of the two-cycle, double-acting engine is complicated, but the number of cylinders is reduced for a given power. On the other hand, in an engine with eight cylinders, one cylinder may not become inoperative without affecting the power of the engine to a very great extent.

It is safe to say that the development of the oil engine in this new role will proceed rapidly. With several German firms building large vessels equipped with oil engines, with the report that the German Admiralty is building a cruiser to be equipped with two six-cylinder engines each of 8,000 horse-power, and with several Glasgow firms building vessels similarly equipped, we shall soon see the oil engine given ample trials.

Revival of the Merchant Marine

To the Editor of the SCIENTIFIC AMERICAN:

I write to express my high appreciation of the great interest which since April 1st you have been manifesting in the upbuilding of the American merchant marine.

Everything published on this subject, either in your editorial or your correspondence columns, is greedily devoured by this writer, who for the past twelve years has made a special study of ship subsidy, mail subsidy, postal subvention, preferential duties, free ships, and every other measure suggested by human ingenuity for restoring that branch of our merchant marine engaged in the foreign or deep-sea trade to the proud position it formerly occupied.

The greatest difficulty in doing this seems to be in getting people living in the interior of the continent, remote from the seaboard, to take an interest in or to inform themselves on such matters.

The writer bids you Godspeed in the work you propose to undertake. JAMES G MCBRIDE.

Canten, Miss.

One Man Who Saw the Meteor Train

To the Editor of the SCIENTIFIC AMERICAN.

Regarding the letter on your page 275 *re* "Meteor Train," I was one of a party of about a dozen at Mamaronsck, New York, who saw the appearance substantially as described by Mr. Pfarre.

Philadelphia, Pa. EDWARD T CHILD.

Lessons of the Gordon Bennett Flying Race

To the Editor of the SCIENTIFIC AMERICAN

With reference to the above subject in your issue of August 19th, will you kindly permit a few supplementary remarks in concurrence with Mr Grover Loening's views thereon? Your contributor lays particular stress upon the difficulty experienced by such able exponents as Weymann and Leblanc in turning sharply at each pylon, and emphasizes on the other hand the facility and also marvelous "banking" performed by Ogilvie on the "Baby Wright."

Now it is certainly correct that this feat is difficult at all times with such superficial area out of all proportion in the case of the 40 square feet surface of the clipped Blériot, but it is also equally certain that the centrifugal force generated by the single tractor-screw is a factor not to be overlooked. That of the Nieuport was 7 feet diameter, the Blériot 8½ feet, while the twin propellers of the Wright are 8¼ feet each, the last however revolving in opposite directions and thus counteracting centrifugal action magnified in the monoplanes. Consequently, the Wright—or its equivalent, a monoplane with twin propellers—is able to "bank" acutely in negotiating turns which would necessitate wide curves with the single-screw type or an alternative loss of stability and disaster. A still further point of importance with monoplanes driven by twin screws is the greater velocity attainable over the biplane similarly propelled, with furthermore the facility to forge against stronger winds—a real desideratum

It is really extraordinary to note at the present moment the continuous copying universally of the Wrights' patent warping system, either flagrantly emulating the bending of the rear marginal tips in conjunction with the foot-operated vertical rudder, or the virtual reproduction of the same by means of ailerons —a system which although copied from nature is by no means the most powerful in controlling lateral stability by the bird. That perfect aviator among other methods demonstrates to us that by warping, or rather *depressing*, the outer half of one wing and correspondingly elevating the othe , he obviates all danger of law litigation by encroaching on the Wright patent!

Well might Mr. Grover Loening in his able article refer to the emphasizing for the need of the "variable surface" monoplane shown by the Gordon Bennett race. Not only will greater speed be accomplished by the adoption of the bird-like wing, but so will inherent or natural stability be automatically secured in tumultuous winds by means of flexible construction in addition to this urgent need for variable surface. Therefore, the lessons demonstrated not only by the Gordon Bennett flying race, but by daily flights throughout the globe, for the production and evolution of the ideal mechanical flying machine, may be succinctly summarised in the following requirements: (1) The improvement of the car or fuselage in finer stream-line Nieuport form; (2) twin propellers of large diameter to thus engage a larger volume of air or "disk area," and rotating in opposite directions to minimise undue centrifugal force; (3) constructing the main planes flexible with small camber, high aspect ratio, and single-surfaced; (4) by superior lateral control other than that employed in the biplane of the Wrights and assured by the graduating of main spars toward the tips; (5) by variable surfacing of main planes or wings to insure higher speeds and susceptibility to encounter safely higher wind velocities by such diminution and augmentation of the supporting area, (6) the discarding of the vertical rudder acting in conjunction with the main planes for steering in the horizontal plane; (7) the need for compactly folding the wings against the side of a car when not in use or descent on water; (8) and the means for increasing or decreasing the angle of incidence of the main planes to suit the requirements of flight conditions All the above essential features are by no means impossible to reproduce in one design, and will decidedly enable a monoplane to ascend and descend from water, and in due course to fly across the Atlantic

London, England. EDGAR E WILSON

The Proposed Safety Stop Locomotive Throttle

To the Editor of the SCIENTIFIC AMERICAN

In the correspondence department of your issue dated August 19th, on page 167, I noticed an article by Aubrey D. Beldelman, of Braintree, Mass., headed "The Bridgeport Railroad Wreck"

In the last paragraph of his communication he offers the suggestion that the throttle and brake-valve handle be provided with means to automatically bring them to positions that would shut off the steam and apply the brakes in the event of the engineer's becoming incapacitated from any cause To quote from his article, "it would be necessary for the engineer to exert some little pressure on them" to prevent their action in this manner

He questions if a device of this kind would be inconvenient. To my mind it would be insufferably so In traversing a rolling country it is necessary for the engineman to frequently change the position of the reverse lever, requiring the use of at least one and usually both hands It is at times necessary for him to use the injector on his side of the engine, due to the inability of the injector on the fireman's side to deliver sufficient water to the boiler

It is not an unheard of thing for an engineman to find it necessary to fill the lubricator while on the road

All these things take time; and while he was at tending to them, the steam would be shut off and the brakes applied, causing a considerable and undesirable reduction in speed

In addition to his physical duties, he has to keep in mind the orders he has received, which govern his movements with respect to other trains that may be on the road, their meeting and passing points, and what time he has in which to make a given point before another train This would be extremely difficult for a man under the continuous physical strain that would be required to maintain these two levers in running position, especially in the case of the throttle as he would have to exert considerable force to hold it open against a device that would have any value as a positive closing mechanism

The conditions under which an engineman works at present are not what might be termed restful There is continual jar and pound, as a locomotive compared to a coach rides about as easily as a hay wagon compared to a limousine

If in addition to this a man were compelled to maintain a steady and unremitting pressure for a period of from three to seven hours, the average length of a passenger run, it would be almost if not quite beyond human endurance.

Los Angeles, Cal. J B WELLS

Irrigation Supplementing Water Power

A New Joint Use for Our Canals.

To the Editor of the SCIENTIFIC AMERICAN

In order to get at the power to be obtained from waterfalls, a height of 10 available feet is taken as a convenient basis to calculate any power from

One cubic foot of water, weight 62½ pounds, falling 10 feet produces 625 foot pounds Requirement for one horse-power, 33,000 pounds divided by 625, gives 53.8 cubic feet, required, for one theoretical horse-power, per minute.

But as wheel efficiency is seldom over 75 per cent, we add one-third to 52.8 or 70.4 cubic feet of water, which is sufficient to cover 844 square feet, or one-fifty-second of an acre So that the amount of water required to produce one horse-power 52 minutes would cover one acre one inch deep, if none was wasted. But as the waste is considerable, let us assume that it requires two hours to cover one acre one inch, or in ten hours the water required to yield one horse-power would cover five acres one inch deep.

Now, as power can be generated, even in small units, for not over 20 cents per horse-power for ten hours, and in large units for much less, we have one inch of water costing four cents per acre, when for some crops it would be worth easily fifty times that, and others much more, as this water is warm rain water, and far superior to well water for irrigation purposes

In view of the above statements, can we not safely conclude that our canals, or at least such sections of them as are favorably located should be maintained for irrigation, which as explained below, may also reduce their value for water powers but little?

In many cases the canal is so located that all the water to be spared can naturally flow onto the lands, while in some cases a ditch to the next lock may be required to get the water high enough

The very favorable results of some small irrigating experiments in our section, I think, will fully justify our valuable experiment stations in examining available located lands, and in preparing necessary information as to suitable crops, fertilizers, sand mixing to lighten heavy soils, etc That may enable the great increase in crops due to irrigating to be fully realized

Now, if the power man, who is usually short of power, either for manufacturing or to sell electrically, will arrange his water wheels, etc, so as to give him the full power of the fall for say the best six months of the year, and will put in engines enough to develop the same amount of power, to be used when there is not water enough for all needed, which if for lighting will be less when water is lowest, he can have water power for all his needs for six months or more, and for nearly all the rest of the time part of the water, in fact most of it Where the water is used only for ten hours for power, the irrigating can be done at night, as in the West So that the power man can be in a better position, after the first cost of engine installment is paid than if entirely dependent on the water power, as he will not only have increased power, but also power that can absolutely be depended on

I trust that the above will be in some way, a suggestion that will be a benefit to the community and the State in making use of its canals

Dayton, O J H STEVENS

Automatic Stability in Aeroplanes—A Suggestion

To the Editor of the SCIENTIFIC AMERICAN

Would you allow me to express through your valuable paper my opinion on the possible solution of the automatic lateral stability in flying machines?

The many devices designed and tried out to maintain automatic stability have as yet not met with the success which would be desirous All further progress and the commercialization of aerial navigation depend upon the appearance of such a device A suggestion of my own may lead to a possible solution of this problem I describe my idea with a view of encouraging constructors of flying machines to experiment in this direction

My automatic lateral stabilizer consists of fins, constructed of a light framework of wood or metal covered with a suitable fabric These fins are hinged under the surface, at the extreme ends of the plane (wing tips) and can swing to both sides When swinging inward such a fin can move until it lies flat under the surface, but toward the outward it is prevented by a strap from swinging farther than 45 degrees

The function of the device may be conceived to be as follows

When the plane is in motion, and as long as it is not influenced by a force caused by a side wind, the fins will be retained in a vertical position But when the wind strikes the plane at an angle to the direction of motion, the fin nearest to the side from which the wind is coming will be laid flat under the surface of the plane At the same time the fin on the opposite side swings outward to an angle of 45 degrees to the plane, and will present a resistance corresponding to the natural resistance on the windward side

This arrangement seemingly works well when straight flights are made, and even in turning it seems likely to do all the banking required, but to straighten out the aeroplane after or at the termination of the turn, it may be found necessary to have recourse to the operation of ailerons Even if this device needs at times to be supplemented by ailerons it would do much to relieve the operator of an aeroplane of the continuous strain which the attendance of a lever mechanism to operate the lateral and the longitudinal stability means

One of the main requirements would be to have the size of the fins in the right proportion to the plane which it serves as equalizer

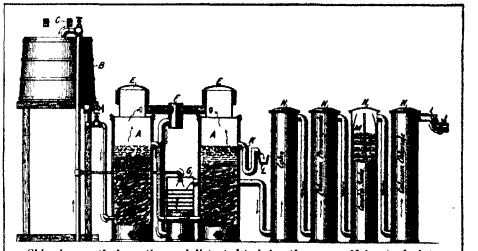
Such a device could be used on aeroplanes of all constructions, and to simplify the attachment of these fins the last five or six ribs on both sides should flatten out gradually, so as to make the extreme ends of the plane nearly flat.

Chicago, Ill. EWALD STEINHAUS

Filling a 400,000 Cubic-foot Balloon

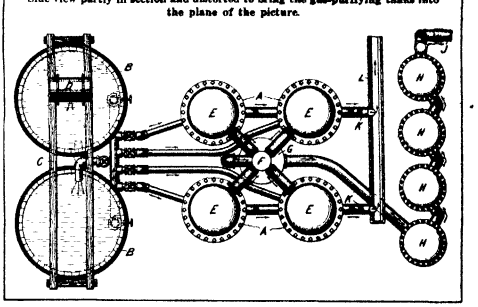
Hydrogen-generating Plant for Vaniman's Transatlantic Expedition

WHO would ever suppose that such coarse, heavy stuff as rusty barrel hoops, iron filings and chips, lathe turnings, and other scraps of the machine shop would enter into the manufacture of the most tenuous and imponderable substance on earth? Of course the initiated know that hydrogen may be made by treating iron with sulphuric acid, and that this is the way that the gas with which balloons are inflated is commonly made. It is the sulphuric acid that contains the hydrogen, the iron serves merely to take up the sulphur and oxygen that form the bulk of the acid, thus liberating the hydrogen. Since in sulphuric acid there is but one part by weight of hydrogen to forty-eight of sulphur and oxygen, a large quantity of acid is required to produce enough hydrogen for an ordinary balloon; and when it comes to such huge airships as the "Akron" with which Mr. Vaniman intends to attempt a transatlantic flight this fall the amount of acid required is enormous. The gas bag of the "Akron" is 258 feet long, and 47 feet in diameter, with a capacity of 400,000 cubic feet. As the average street blocks of New York measure 250 feet and the width of Broadway downtown is but 40 feet from curb to curb, some idea of the huge bulk of the balloon can be obtained. To fill this huge gas bag a large plant was built at Atlantic City. Nearly 80 tons of scrap iron was carted to the plant and 100 tons of sulphuric acid in large casks, containing over 16,000 pounds each. These materials were capable of producing 450,000 cubic feet of hydrogen gas. An equal quantity of coal gas would supply an average town of 10,000 inhabitants for three days and if the gas were fed to an ordinary five-foot gas burner, it would take more than ten years to exhaust the supply. For five days and nights the plant operated continuously generating hydrogen, which was carried directly into the huge gas bag.



The bag is made of three thicknesses of cotton cloth, gummed together with thin layers of rubber, and its total weight is considerably over two tons. This, of course, is the weight of the bag in air when not inflated. It is always confusing to speak of weights when referring to a balloon. It is difficult to conceive that the hydrogen in the balloon has any weight, and yet if the balloon were in a vacuum it would crash to earth with a tremendous impact, for not only does the envelope weigh many thousand pounds, but the gas itself would weigh over a ton.

The accompanying drawings, which are somewhat diagrammatical, will serve to illustrate the process of producing the gas for the "Akron." One is a true plan view of the plant, and the other a distorted elevation, partly in section.



Those who are acquainted with the usual methods of generating hydrogen for balloons will notice a number of innovations introduced by Mr. Vaniman, whereby there is no interruption in the generation of the gas. As indicated in the plan view, there are four generator tanks *A*, which are made of wood with all the iron parts well coated with pitch to prevent the sulphuric acid from attacking them. These tanks are partly filled with scrap iron. The sulphuric acid is fed into the tanks from one of two large reservoirs *B*. Over the reservoirs is a track *C* on which the sulphuric acid cranks *D* are supported. In order to prevent too rapid a generation of gas and choking of the tanks with ferrous sulphate, the sulphuric acid is diluted.

For every part of sulphuric acid, eleven parts of water are used. While this mixture is being prepared in one of the reservoirs the other is tapped and the dilute sulphuric acid takes the course indicated by the arrows to the bottom of the generator tanks. It may flow directly into any one of these tanks or may be made to flow from one pair of tanks into the other. The latter is the more economical method, as it ensures complete action of every particle of the acid. The gas generated in the tanks rises to the top, where it is trapped by gasometers *E*, and flowing into a common chamber *F*, passes down to the washer *G*. Here it is forced to make its way upward through a series of perforated plates, while a spray of water flows downward through the same plates. Thence the gas passes through four tanks *H*, the first containing coke, the second potassium permanganate, the third caustic soda, and the fourth calcium chloride. The first two serve to purify the gas of such materials as arsenic, sulphur and phosphorus, which are apt to be picked up from the iron. The other two tanks serve to remove all traces of moisture from the gas.

Hydrogen is an odorless, colorless gas, and it would be impossible to detect leaks in the balloon were not some means used to impart an odor to the gas. The "perfume" commonly used is muronine. This is placed in a sponge as indicated at *I*, and thence the gas is fed directly into the balloon through the tube *J*. The "perfume" used has a most penetrating sickish odor, that can readily be detected, no matter how small the perforation in the bag through which the gas is escaping.

Side view partly in section and distorted to bring the gas-purifying tanks into the plane of the picture.

Plan view of the hydrogen-generating plant; course of liquid shown by straight arrow, course of gas by crooked arrows.

One of the advantages of the arrangement shown in the drawing is that when it is desired to charge one of the generators with fresh scrap iron it may be cut out of the system completely by turning off the pipe conducting the sulphuric acid to it and also placing a clamp on the rubber hose connecting the gasometer of that particular generator with the chamber *F*. The spent liquor flows from the generators through traps *K* to a trough *L*, which leads to a large trench or drain.

Heretofore the purifying and drying tanks have been filled with coke in which the various cleansing chemicals were sprinkled, the purpose of the coke being to prevent the materials from clogging. This method has caused much trouble because the materials would slowly gravitate to the bottom of the tanks, choking the flow of gas. Whenever such a condition arose, it was necessary to shut down the entire plant and clean out the tanks. Mr. Vaniman has adopted a different method. He uses a set of trays of copper netting secured to iron straps, as indicated at *M* in the drawing, and on these trays the purifying and drying materials are placed. Thus the mass is kept in a porous condition, through which the gas can easily percolate, and in case of any trouble the entire set of trays can be lifted out bodily.

The Trade Winds of Porto Rico

DR. O. L. FASSIG, of the United States Weather Bureau, is one of America's few able climatographers, and is well known for his exhaustive treatises on the climate of Maryland and of the city of Baltimore. For the past two years he has had charge of the Weather Bureau station at San Juan, Porto Rico, and he has of late published a number of useful and timely monographs on Porto Rican climate. The latest, which appears in the *Monthly Weather Review*, deals with the trade winds.

Although the trade winds of the northern hemisphere are commonly supposed to blow from the northeast, this is hardly their prevailing direction in the West Indies. In Porto Rico their general direction, taking the year as a whole, is between east and southeast, though the percentage of northeast winds increases during the winter. As to diurnal variations, the prevailing direction during the daytime (9 A. M. to 10 P. M.) is east, while during the night, after 10 o'clock, it is southeast. This applies to the year as a whole, but during July and August the prevailing east wind extends far into the night; viz., to 1 or 2 o'clock in the morning.

The average hourly velocity of the trade winds for the year is a little under 11 miles, the monthly values ranging from 8 miles an hour in October to 13 miles in July. On an average these winds are lightest about sunrise and strongest about 2 o'clock, at San Juan. The trade winds of course never rise to the force of a gale, and the few high winds that occur in Porto Rico are generally due to the passage of tropical cyclones.

Judging from the movement of clouds over San Juan, the average depth of the trade-wind current in this region probably does not exceed 10,000 feet. The upper clouds—the cirrus forms—have a nearly uniform movement from the western quadrant; that is, they show that the upper air current is opposite in direction to the trades.

The trade winds contribute greatly to the good health and comfort of the inhabitants of Porto Rico. In fact, it is the presence of the steady, moderate flow of the trades that takes this island out of the class of areas in the tropics to be avoided by white men, and makes it for more than half the year a very desirable place of residence for business as well as for pleasure.

The utilization of the trade winds as a source of motive power is gradually receiving proper recognition, and the number of wind-mills is increasing. The south side of the island is comparatively dry, and the rainfall is irregularly distributed through the year, necessitating extensive irrigation operations; while on the north side the drainage problem is almost equally important. In both these operations wind-driven pumps might be used to great advantage.

Nature's Parachutes

CAREFUL examination has been made of the heads of Canada thistle-downs, in order to determine their effectiveness as parachutes, carrying the seeds of the plant to great distances through the air. The results of this examination are quite remarkable.

Calculation shows that a thistle-down starting from an elevation of 10 feet, in still air, would require two-thirds of a minute to reach the ground. With a wind blowing 30 miles an hour it would be carried, on the average, about a fifth of a mile. The total surface exposed to the air in an average thistle-down is, on account of the great number of bristles, a little more than one-third of a square foot. Another well-known and very beautiful example of nature's parachutes is furnished by the light silken threads with the aid of which the little gossamer spider makes long aerial voyages.

Suggestions for the Workshop

Ingenious Expedients of Resourceful Mechanics

Handy Man's Medicine Chest

To the Editor of the Workshop Department:

In looking over Handy Man's Medicine Chest, in the issue of September 9th, I notice that the collodion dressing with aristol or iodoform added calls for 50 grains to the ounce. I intended this to read 50 grains. This amount would do more harm, but as there are only 31.1 grammes to the ounce, by using 50 grammes of aristol you have more aristol than collodion, which I fear would be an almost useless mixture. The mistake of reading grams for grains is often made by druggists, and for this reason I believe that when grammes is intended, it should be written out in full (grammes).

WILLIAM R. INGHAM, M.D.

Dangers of Gasoline Vapor Cleaning

To the Editor of the Workshop Department:

The description of an automobile cleaning device published among the "Suggestions for the Workshop," on page 276 of September 23d issue, is of considerable interest from an insurance point of view, from the fact that *the vapor from one pint of gasoline will make 200 cubic feet of air explosive*. The device seems to be an excellent gas generator; a flame some distance away will ignite the vapor, and the operator of the cleaner will never know what hit him.

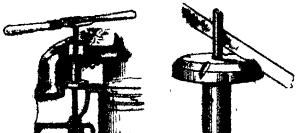
Would it not be well to caution your readers against the use of such a dangerous machine?

F. D. C STEWARD.

Holder for Filing Small Screws

By R. F. D.

WHEN a small screw is to be filed down to shorten it, it is not advisable to put it in a vise for fear of damaging the threads.



Holder for filing small screws.

A small piece of soft iron may be bent and drilled in the manner shown in the illustration, and then screwed or nailed to the bench top with the screw in the position shown.

Refacing Valve Seats

By Albert F. Bishop

WHEN refacing the valve seats of an automobile engine, it is usually the practice to make a reamer out of cast steel and temper and grind it to size. This is rather a tedious task and somewhat expensive. Recently a friend of the writer found it necessary to reface the valve seats of his four-cylinder automobile engine, which meant that there were eight valves to be treated. Instead of adopting the usual method, the writer suggested that he make his reamer of soft steel, and fit it with cutting edges by sawing through the beveled edge of the reamer with a hack saw in four places and driving in four pieces of clock spring. These cutters were filed down nearly

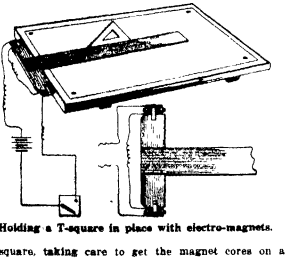
Reamer for regrinding valve seats.

to the surface of the reamer. The bevel was finished in the lathe with the grinder, allowing the clock spring strips to project about 0.02 of an inch, or less, from the surface. Small grooves were filed in the reamer in front of the cutting edges to allow for clearance of chips. The lower end of the reamer was made to fit nicely in the guide for the valve seat. One of the rings in the engine directly over the valve was bored out to fit the upper part of the reamer. This plug not only held the reamer accurately, but also acted as a stop, for it could be screwed down as the reamer was lowered. The eight seats were refaced with perfect ease, the last one cutting as well as the others. When the work was completed, the hole bored in the plug was stopped up with a piece of metal, and the plug was replaced in the engine for service. The valves were placed in the lathe and faced off enough to true them, after which they were inserted in the engine and ground to a fit with powdered glass and oil.

Laying Out Work for Drilling

By George F. Brown

A QUICK and accurate way of obtaining an impression of the holes already drilled in a flange when a new flange or cap is to be fitted to it, is to rub a piece of chalk down into the hole so that the edge will scrape off a small amount, forming a bead of chalk that is slightly raised above the surface of the flange. On the flange thus prepared the new flange is laid in



Laying out work for drilling.

the exact position in which it is to be bolted. On removing the chalked flange an accurate tracing of each hole will be found on the new flange. These circular tracings can be centered and drilled and they will be sure to mate the holes in the other flange when it is replaced for bolting.

Magnetic T-Square

By William Grötzinger

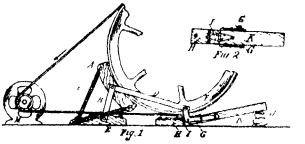
WHEN much hatching is to be done there is always a tendency to move the T-square out of position because it is necessary to hold the T-square and at the same time to manipulate the triangle and the ruling pen. To eliminate this trouble the writer took two small electro-magnets out of an old door bell, and fastened one on each end of the head of the

Holding a T-square in place with electro-magnets.

T-square, taking care to get the magnet cores on a line with the edge of the head.

Then a piece of thin iron band was fastened to the edge of the drawing board with several small screws. The magnets were connected in series with a battery and switch. When turning on the current, the magnets will hold the T-square firmly against the drawing board. Then all one needs to do is to attend to the triangle and the pen. This will eliminate slipping of the T-square and make for accurate work.

Flywheel Brake



By C. M. Moon

THE brake illustrated herewith was designed for use on the flywheel of a heavy Gordon job printing press, having the driving motor belted to the flywheel. It was necessary to construct the brake in such a way that the parts would not interfere with the driving belt.

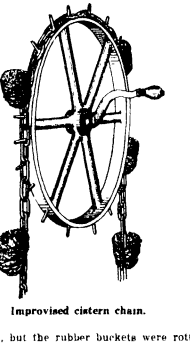
As will be seen by referring to the illustration, *M* represents the motor; *A* is the brake shoe, which is supported by two legs, *B*, with the belt passing between them. These legs are bolted to the block *E* which is securely fastened to the floor. The coil springs *C* assist in holding the brake shoe away from the wheel, and also keep the ends of the shoe from rubbing. The brake shoe is connected by means of two drawbars *D*, one on either side, with the two bell cranks *G* which are screwed to the sides of the foot lever *K*. These bell cranks, drawbars, and brake shoe legs are made from ⅝ inch band iron, ¼ inch thick.

The foot lever is connected with the block *H* by means of a 6-inch strap hinge *I*, as will be noted in Fig. 2 of the sketch, and the block *H* is securely fastened to the floor with lag screws. The coil spring *J* holds the outer end of the foot lever about three inches above the floor, and also assists in holding the brake shoe away from the flywheel, except when stopping the machine. The spring used was an old-fashioned bed spring, which answers the purpose very well.

The brake shoe, foot lever, and floor blocks should

Flywheel brake.

be made of hard wood if possible, but any kind will do the work. If desired, the shoe may be faced with a piece of leather belting, smooth side outward, which gives it a much better grip on the wheel.



This brake is very powerful on account of the leverage obtained at the foot lever, and also because of the fact that the brake-shoe legs are not placed perpendicularly, but incline somewhat toward the flywheel, thus when the brake is applied, the friction tends to force the shoe more tightly under the wheel.

With this device the machine may be brought to a stop slowly, or in case of accident almost instantly, by increasing the pressure upon the foot lever.

Repairs to a Cistern

By J. W. Romig

A FRIEND of mine has a traction engine and one day while on the road he found that he had very little water left. Just at this time they were passing an old deserted house whose cistern was about half

Improvised cistern chain.

full of water, but the rubber buckets were rotted off, so taking some cotton waste from the engine he made buckets with this, and got enough water to complete his run.

Workshop Notes

To Sharpen Chisels.—Often one has chisels of awkward shape, and no stone with which to sharpen them. If a piece of wood is cut to fit the chisel, it can be used in place of a stone, by dipping it in a mixture of oil and powdered emery, and then manipulating as an ordinary stone.—B. FRANCIS DASHIELL.

Soldering Galvanized Iron.—Raw soldering fluid is generally used on the soldering copper when it is desired to solder galvanized iron. However, before commencing to solder, it is desirable to dip the soldering copper while hot in a solution of salammoniac and water. This will retain the tin on the point of the soldering copper, which would otherwise soon disappear.—A. F. B.

Disposition of Guns in Dreadnoughts

Foreign Navies are Adopting the American Center-line Plan

By Percival A. Hislam

With total number of ships of the all-big-gun type now built, building, or provided for in the current year, is exactly one hundred Great Britain leads with thirty-two (which includes two cruisers building at the cost of Australia and New Zealand), followed by Germany with twenty-one, and the United States with twelve. Japan, having this year placed orders for no fewer than five ships of the type (one building in England and four to be laid down in Japan), has increased her total to seven Russia, France, Italy and Austria have four ships apiece, none being yet completed, and the first named power proposes as soon as possible to raise her total to twelve Brazil and Spain each possesses three "Dreadnoughts," two of the Brazilian ones being completed, and the list is completed by the Argentine Republic, with two ships on the stocks, Turkey with two recently ordered in England, and Chili with two which are shortly to be placed out to contract

In this total of a hundred ships there are thirty one whose details either have not yet been decided upon or are not yet known The policy of secrecy, inaugurated by Great Britain with her pioneer "Dreadnought," has been followed by several other powers Germany conceals the particulars of her new warships very successfully, and only nine can be spoken of with any certainty. Latterly, Great Britain has relaxed the policy and the only vessels whose details are uncertain are the five of the 1911 12 programme Nothing is known of this year's quintet of Japanese ships except that they will carry 13.5 inch guns, and other ships where similar lack of certain knowledge exists are the new American vessels to be laid down this year (which, it is expected, will have ten 14-inch guns in two twin and two triple turrets), the last two of the four Austrian vessels, the Turkish and Chilian ships, and the Brazilian "Rio de Janeiro" The last-named vessel was for some time reported to be designed to carry twelve 14.5-inch, fourteen 6 inch, and fourteen 4-inch guns but it has latterly been stated that she will after all be no more than a replica of the "Minas Geraes" and "Sao Paolo"

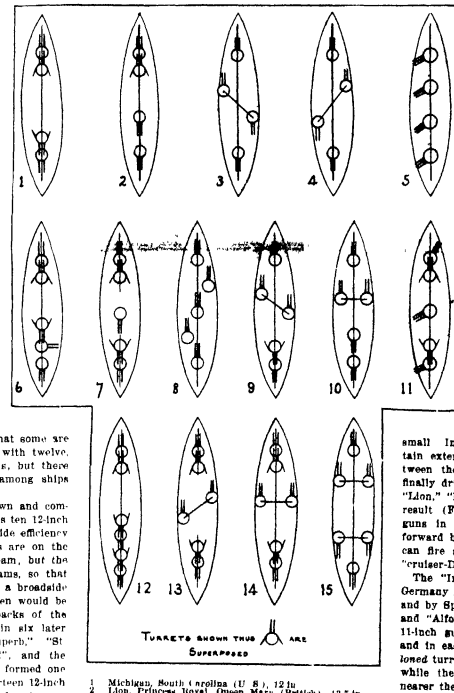
In the case of the sixty-nine ships whose principal details are known, there is a very wide divergence in the mounting of the main battery This would necessarily follow from the fact that some are armed with eight, some with ten, some with twelve, and three even with thirteen heavy guns, but there are also considerable differences even among ships with the same number of guns

The first "Dreadnought" to be laid down and completed—the British ship of that name—has ten 12-inch guns so arranged as to produce a broadside efficiency of 80 per cent (Fig 10) Three turrets are on the center line and so can bear on either beam, but the other two are placed abreast on the beams, so that each can bear on only one broadside In a broadside engagement, therefore, two guns out of ten would be useless In spite of the obvious drawbacks of the arrangement, however, it was repeated in six later ships—"Bellerophon" "Temeraire," "Superb," "St Vincent," "Collingwood" and "Vanguard", and the result is that these seven ships, if they formed one battle unit, would have no fewer than fourteen 12-inch guns out of seventy useless for a line-ahead action

These seven British ships are the only five-turreted dreadnoughts which cannot dispose 100 per cent of their heavy guns on the beam The American five-turreted ships "Delaware" "North Dakota," "Florida," and "Utah" (Fig 6) have all their turrets on the middle line, with the result that these four ships, mounting ten 12 inch guns apiece and forty in all, are equal in broadside action to five of the British ships mounting fifty 12 inch guns, since only forty of these could be brought to bear on the beam We are not dealing here with secondary batteries; but the best five of these seven British ships mount ninety-two 4-inch all told (twenty each in the "St Vincents," and sixteen in the "Bellerophons"), while the four American vessels have sixty 5-inch, which, allowing for the much greater power of the 5-inch gun, is in all probability a superior equipment. In her later vessels Great Britain began to show signs of being influenced by the full-broadside argument. Its force was, however, admitted grudgingly, and a wavering effort made to combine a full broadside with a heavy fore and aft fire The "Neptune," "Hercules," and "Colossus" were the result (Fig. 9). These ships, like the earlier "Dreadnoughts," have three turrets on the middle line, but the wing pair are placed *e. échelon* across the deck amidships, while the last turret but one from aft is super-posed to fire over the aftermost The result is that six guns can be fired ahead and eight aft is superposed to fire over the aftermost. The be covered by all ten guns. Over a large angle, however, the fire of the port turret is masked on the starboard side by the starboard turret, and *vice versa*, and the lengthy experiments which were carried out in the Mediterranean early this year are believed to have proved that the compromise is not a very happy one.

At any rate, it has been abandoned in later ships The "Orion," "Thunderer," "Conqueror," and "Monarch" (1909-10 programme), and the "King George V.," "Centurion," "Ajax," and "Audacious" (1910-11 programme), will have ten 13.5-inch guns in five turrets, all on the center line. The second from forward will be superposed, so that four guns will bear forward; and the same arrangement is repeated aft, the fifth turret being amidships (Fig. 7). In these ships, therefore, Great Britain for the first time acknowledges the superiority of the all-on-the-center-line system which has been applied to American "Dreadnoughts" since the first was designed. The ten 14-inch guns of the "Texas" and "New York" will be mounted on this plan.

The last of the known five-turreted ships are the Italian vessels "Conte di Cavour," "Leonardo da Vinci," and "Giulio Cesare." In the case of the last two it is possible that the original design may not be adhered to, but they were all designed to carry, and the "Conte di Cavour" at any rate will be equipped with, thirteen 12-inch guns arranged as shown in Fig. 11 of the diagram. There will be three three-gun turrets, one forward, one aft and one amidships, and two twin-turrets will fire over the fore and aft turrets respectively. There will thus be a full broadside fire of thirteen 12-inch guns, while five will bear ahead and astern. If this arrangement is not carried out in the other two ships it will be to allow of the mounting of heavier guns. It may be mentioned that the guns in the triple-turrets are arranged on two levels, two being below, and the third above and between them In this way the breadth of the turret is saved at the cost of additional height.



There are comparatively few four-turreted "Dreadnoughts." The first were, of course, the American "Michigan" and "South Carolina," although for various reasons they were not at sea until after the British "Invincible" cruisers The "Michigans" have eight 12-inch guns in four turrets, two forward and two aft, the one nearer the middle of the ship being superposed in each case (Fig 1). The British "Invincible," "Inflexible," and "Indomitable" also have a nominally full broadside (Fig. 3), two turrets being on the center line, and two *en échelon* amidships; but the latter (as in the "Neptune") are so close together that the arc covered by eight guns is very small In the "Indefatigable" this fault was to a certain extent remedied, by increasing the distance between these two turrets; but the authorities were finally driven to adopt the American system, and the "Lion," "Princess Royal," and "Queen Mary" are the result (Fig. 2). These ships have eight 13.5-inch guns in four middle-line turrets, the second from forward being superposed Only two guns, therefore, can fire aft, as compared with six in the previous "cruiser-Dreadnoughts" built for the British navy.

The "Indefatigable" system has been followed by Germany in the case of the "Von der Tann" (cruiser), and by Spain in the battleships "Espana," "Jaime I.," and "Alfonso XIII." The "Von der Tann" has eight 11-inch guns and the Spanish vessels eight 12-inch; and in each the longitudinal space between the *échelonned* turrets is much more than in the British ships, while the starboard turret, instead of the port, is nearer the bows (Fig 4). The British cruisers "New Zealand" and "Australia," building for Pacific service, are similar to the "Indefatigable."

The other known four-turreted ships are equipped on the triple-turret system, which has lately come into considerable vogue All are armed with twelve 12-inch guns, their names and nationality being: "Petropavlovsk," "Poltava," "Sevastopol," and "Gangut" (Russian), "Dante Alighieri" (Italian), and "Viribus Unitis," and a vessel at present known as "V" (Austrian). It has been rumored that in the case of the Austrian ships two turrets will be superposed, but this lacks confirmation (Fig. 5).

"Dreadnoughts" with six turrets are again comparatively few in number, but present some striking contrasts. The American "Wyoming" and "Arkansas" have twelve 12-inch guns in six center-line turrets, two forward and four abaft of the superstructure.

THE DISPOSITION OF GUNS IN DREADNOUGHTS

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

Atmospheric Pressure in Past Geological Ages

THE modern development of aviation suggests the question whether the atmosphere of the earth was denser during the carboniferous epoch than at the present day.

This subject is briefly discussed by a writer in *Cosmos*, whose remarks we reproduce here.

"Among the animals which people the earth we find representatives of all sizes, from the microscopically small animalcule to the great elephant. But within the limits of any one species the scale upon which the individuals are built does not differ very materially; we do not, for example, find specimens say ten times larger than their adult congeners

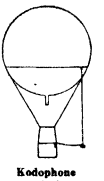
"It is easy to show good mechanical and physical reason why this should be so. Consider two birds, geometrically similar, such as two swallows for example, and imagine the second to have ten times the normal size. This bird will then have all its linear dimensions ten times as great as the normal bird, while the surfaces will be one hundred times as great In this way all the cross sections, the thickness of the muscles, especially of the wing muscles, being increased one hundred fold, we may safely take it that the strength of the bird will also be increased in the same proportion. But on the other hand, it must be remembered that the volume, and hence the weight of the body, will be increased one thousand fold. Thus this large swallow, built on ten times the normal scale, would find itself quite unable to rise into the air or to sustain itself there, for it is relatively ten times less strong than its congeners: with muscles one hundred times as strong as theirs it is called upon to perform one thousand times the work.

"As a matter of fact, an examination of the flight of different kinds of birds having approximately the same form shows that flight becomes more and more difficult as the weight increases; large birds substitute as far as possible sailing flight (which is the characteristic motion of our aeroplanes) for flapping of the wings Thus the size of animals capable of flight has an upper limit, and this seems to be reached, in the present state of nature, by the large birds, so far as sailing flight is concerned, and by the large insects, so far as flight by wing vibration is concerned

"And yet in past ages much greater animals have flown. One reptile of the group Pterodactyl had a span of over thirty feet, which exceeds that of a racing Blériot; this creature lived during the cretaceous period and flew as far as 90 miles inland Certain dragon flies of the carboniferous era measured over three feet from tip to tip of their outspread wings. Under present conditions it would be quite impossible for these creatures to fly. The most natural supposition is that in the times when these creatures flew through the air, the atmosphere had a greater density than it has at present. This is the conclusion reached by Mr. Harle In the estimation of this paleontologist, the existence of these great flying animals during cretaceous and carboniferous times indicates that atmospheric pressure at that time was greater than at present."

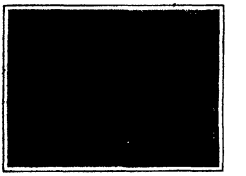
The Autogenous Cutting Process in Handling Wreckage

FOR some time past, the well-known autogenous fusing process (oxy-acetylene blowpipe) has been used with great success for clearing up wreckage after fires, explosions, and similar accidents An interesting case occurred in a town in Germany, where a school building in the course of construction collapsed, burying a number of workmen under the debris. As good fortune would have it, an oxy-hydrogen cutter happened to be available in the immediate neighborhood, and with its aid the iron parts were cut through in short order, and the workmen were extricated from their hazardous position.



The importance of the oxygen blast is, of course, still greater in cases in which the construction is entirely made of iron. Thus, for instance, it was very extensively used in clearing up the wreckage after the collapsing of a large gasometer in Hamburg in December, 1909.

The lightning rapidity of the cutting burner is of particularly great utility in the case of railway disasters, where it is essential that the work be performed as quickly as possible so as to clear the road. At the present day, numerous railway corporations have adopted autogenous cutters as a part of the equipment of their wrecking cars. Municipal fire departments also have installed this apparatus.



In Germany the process is almost universally carried out with hydrogen and oxygen instead of acetylene and oxygen, because the hydrogen is readily compressible into steel bottles, while acetylene cannot be thus stored without special precautions, since it is liable to explode.

The Kodophone

IT is very desirable for an aeronaut to know the vertical velocity of his balloon, relatively to the air Instruments for indicating this relative velocity have been invented by Neumann and by Lentz The name Kodophone has been given by Lentz to his instrument, which is described as follows in *Prometheus*: A small windmill is suspended from the balloon, with its plane of rotation horizontal, in the manner indicated in the diagram. The windmill is connected by wires with two electric bells of different pitches and a battery, contained in a case which is attached either to the side of the car or to the suspension ring above the aeronaut's head The connections are made in such a manner that one bell sounds when the balloon rises, and the other when it sinks, relatively to the air The velocity of relative ascent or descent is indicated by the length of the interval between successive strokes of the bell This automatic device is especially valuable at night and at any time when the aeronaut's attention is distracted for any reason.

Kodophone attached to balloon.

The Kodophone.

A Practical Manufacturer on the Synthesis of Rubber

IN the May number of the new journal *Kunststoffe*, Dr. Gerlach-Hannover, a practical rubber manufacturer, makes the following statement

"The problem of producing caoutchouc synthetically has been solved. But just as in the case of indigo 20 years elapsed before the synthetic product was successfully launched, it will take at least 20 years before synthetic rubber will make its appearance commercially. It will take perhaps longer with caoutchouc because the physical properties of this material are not as well known as those of indigo The high price of the natural product stimulated research and, after the pioneering experiments of Harries, the Elberfeld Farbenfabriken have finally succeeded in producing larger quantities of a product derived from a material closely related to isopren At this stage of the development it was found out that there exist many sorts of rubber which are near relatives but still possess different characteristics

"The first synthetic caoutchouc which was placed at my disposal, for example, did not unite with sulphur and had a leathery appearance This was not to be wondered at, as there are known some varieties of natural caoutchouc which cannot be vulcanized Soon another sort of rubber came to my notice which showed better affinity for sulphur, but still could not be perfectly vulcanized Above all it lacked elasticity Soon, however, larger quantities of a third sort were submitted to me which to my great astonishment showed all the excellent properties of natural rubber.

"But now the question arises whether this material of the Elberfelder can be economically produced on a large scale and may thus become a danger for natural rubber. It cannot be denied that the substance, which possesses good qualities, can be utilized for practical purposes. Its price is not high but it is a complex question to decide whether this synthetical product will become a danger to natural rubber All kinds of economical and commercial conditions must be taken into consideration One thing, however, is certain, that synthetic rubber will soon be a commercial article"

Highway Engineering as a Profession

ACCORDING to Prof Arthur H Blanchard, who recently lectured before the Society for the Promotion of Engineering Education, the technical graduate who is attracted to highway engineering has several more or less well-defined fields open to him These are

"The highway departments of municipalities and towns, those of States, counties and parks, the engineering organizations of contractors, and the engineering and sales departments of companies dealing in materials and machinery used in highway work In city and town work matters relative to the construction and maintenance of streets and pavements compose the bulk of the work assigned to the highway departments, together with more or less road engineering problems With State, county and park departments, the construction and maintenance of all types of road surfaces and bituminous pavements constitutes 90 per cent of the work of such organizations, while certain problems in street pavements and highway bridges have to be dealt with occasionally The prevailing idea, however, that the two fields just mentioned are easily separable, and that the preparation for one should not be the preparation for the other, is essentially wrong Since the lines of demarkation between the above fields are rapidly becoming obliterated, the successful highway engineer of to-day, whether engaged by the city or State, must have a comprehensive knowledge of all branches of highway engineering and allied subjects Otherwise it is obvious that it will be impossible to follow that important principle of economics of highway engineering, the adaptation of methods and materials to local conditions

"In contemplation of these opportunities, the essential prequisites of a successful career as a highway engineer must be given due consideration in order that the future prospects offered by this field of engineering may be thoroughly understood"

Prof Blanchard recommends four years' training in a course in civil engineering, practical experience in both field and office in connection with the construction and maintenance of roads and pavements on a system of highways, and the acquisition of knowledge along certain lines of particular value to the highway engineer, by which last is meant knowledge of the economics of highway engineering materials of highway engineering, management engineering, highway laws and systems of administration, mechanical appliances used in highway engineering, highway bridges and culverts, road and street surveying, drafting and designing, methods used in road material laboratories, advanced dynamic and structural geology, lithology, petrology and petrography, processes of industrial chemistry, methods of testing bituminous materials and the interpretation of results, and finally advanced highway engineering covering the most recent practice throughout the world in the construction and maintenance of all kinds of roads and pavements

The problem before the educational institutions of this country is that of determining by what method the subjects outlined above can be offered upon a practical basis Prof Blanchard does not favor a four years' undergraduate course in highway engineering, partly because undergraduate students are not sufficiently mature to acquire the benefits which should be derived from a combination of practical experience and specialized knowledge

The most practicable plan is to arrange a definite course of instruction as a unified graduate course based on the assumption that the technical graduates enrolled for the master's degree will hold undergraduate degrees in civil engineering If the graduate instruction is to be given in the period from about December 1st to about April 1st, it will be possible for practising highway engineers, especially first, second, and third year graduates, to use the winter period advantageously in acquiring advanced knowledge under favorable circumstances

Columbia University will offer a course next year which will cover the field of subjects referred to in Prof. Blanchard's paper, and will in amount, be sufficient to satisfy the requirements for the master's degree

The Heavens in October

Some Difficulties in Plotting Comets' Orbits

By Henry Norris Russell, Ph.D.

ALMOST the only real difficulty in preparing such articles as these arises when a new comet is discovered. To give a detailed account of its motions during the ensuing month, the writer must have before him an ephemeris of the comet's place for the next five or six weeks, and this is not always forthcoming. An approximate orbit is indeed usually calculated by the time a comet has been in sight for a week, and its motion predicted by the end of this for two or three weeks more. But these preliminary orbits are often not very accurate. The difficulty may be illustrated by that of finding the exact size and position of a circle which passes through three points, *A*, *B*, and *C* close together and nearly but not quite in line.

If we suppose that the position of the point *B* has been observed and that a slight error has been made placing it at *B'* instead of its real position, our calculations will lead us to the circle *A B' C D'* instead of the correct circle, *A B C D*. Within the region covered by the original observations, the two circles will be quite close together, but outside this region they will deviate from one another at an ever-increasing rate.

The mathematical processes involved in calculating a comet's orbit are closely analogous to this simple case, though much more complicated. It is, therefore, easy to see that a small error in one of the observed positions of the comet, on which the calculations are based, may give rise to an enormously greater error when the attempt is made to predict, by means of these calculations, where the comet will be after an interval of time ten times as great or more, than that covered by the original observations.

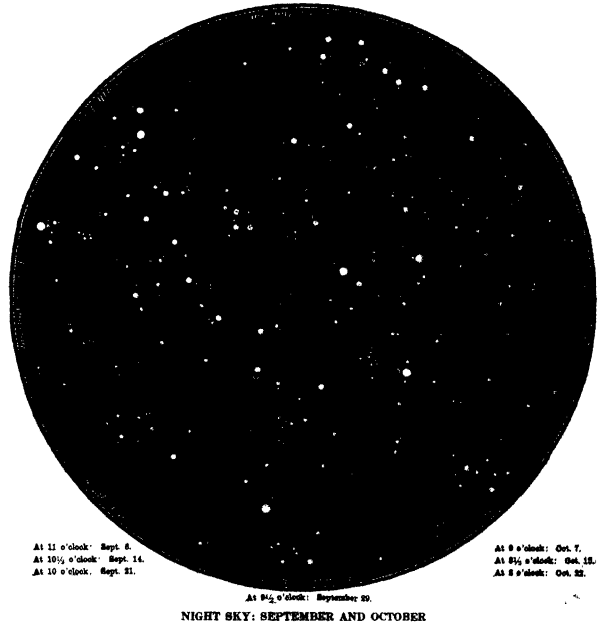
It is therefore not worth while to use the preliminary orbit of a comet to predict its motion for more than two or three weeks. Before the end of this time, many more observations can be secured, and an improved determination of the orbit made (just as, in our diagram, it is evident that, if we had observed the positions of two or three more points on the circle between *C* and *D* even with errors as large as that made in the case of point *B*, the whole set of such observations would suffice to fix the position of the true circle with considerable accuracy).

For these reasons it is the exception, rather than the rule, when an ephemeris predicting a comet's position till the end of a given month is available by the 15th or 20th of the preceding month, and this explains why the predictions concerning newly discovered comets, appearing in these columns, may sometimes appear vague.

Brooks's comet, mentioned last month, is a case in point. In this instance too, the early estimates of brightness seem to have been too low. The comet has not only become visible to the naked eye but fairly conspicuous.

Its orbit is now pretty well determined, perihelion passage occurring near the end of October, at a distance of some 40 million miles from the sun.

During the early days of the month it will be visible in the evening sky, though the moon, then in her second quarter, will interfere with observation. There ought, however, to be no difficulty in identifying the large diffuse head of the comet with a field-glass.



Later in the month it passes between the pole and the sun, and for a few days will be visible both in the evening and the morning, low in the northwest after dark, and low in the northeast before dawn. At the time of perihelion, toward the end of the month, it will be in Virgo, rising more than two hours before the sun, and should be a fairly conspicuous object after new moon, when the morning skies are dark.

Slight shift of B makes very different curve

THE HEAVENS.

At the hour for which our map portrays the appearance of the sky the Milky Way forms a vast arch passing almost through the zenith. Along this are many fine constellations—Sagittarius, low in the southwest; Aquila, well up in the same quarter, Cygnus, almost overhead, but a little west of the zenith; Lyra, west of this; Cassiopeia, high in the northeast, the less conspicuous Cepheus, just above the Pole star; Perseus, at a moderate altitude in the northeast; and finally Auriga, just rising below him.

At 8½ o'clock: Oct. 15.
At 8 o'clock: Oct. 22.

NIGHT SKY: SEPTEMBER AND OCTOBER

The Great Bear is low on the northwestern horizon, and the Dragon, coiling around the Little Bear, is higher up. Boötes has almost set in the northwest, and Corona is very low. Hercules is a little higher, on the way toward Lyra. Ophiuchus and Serpens are also represented by only a few stars in the west.

Capricornus and Aquarius fill a large, dull region in the southern sky. Below them is an isolated star, which from its very loneliness seems all the brighter. This is Fomalhaut, the only conspicuous object in the constellation of the Southern Fish. A nearby horizontal line of five stars of the fourth magnitude, not shown on our map, but visible easily enough on a clear night, form the remainder of the constellation.

Fomalhaut is of some interest as being within a measurable distance, though not one of the very nearest stars. Its parallax is 0.14 second, corresponding to a distance of 26 light years, and its actual brightness is about fifteen times that of the sun.

Below Fomalhaut, and now on the meridian, is the far southern group of Grus, the Crane. Its two brightest stars, of the second magnitude, barely rise above the horizon of New York, but it is a conspicuous constellation in lower latitudes. The great square of Pegasus is close to the zenith, on the southeast. Andromeda is just to the left with Triangulum and Aries below her. Taurus is rising, a little north of east. Cetus and Pisces fill the southeastern sky.

THE PLANETS.

Mercury is morning star until the 23rd when he passes behind the sun, and becomes evening star. He rises about an hour and a quarter earlier than the sun at the beginning of the month, and should be fairly easy to see. By the 15th he is lost in the sun's rays, and remains so until November is half over.

Venus is likewise a morning star, but is much farther from the sun, and exceedingly conspicuous—reaching her greatest brilliancy on the 21st. She rises about 4:15 A. M. on the 1st, and just before 3 A. M. on the 31st. At 1 P. M. on the 18th she is in conjunction with the moon. Though 7½ degrees south of the latter, she can then be easily found with the naked eye—her great brightness making her clearly visible, even at noon.

Mars is in Taurus, not far from Aldebaran, rising about 8:30 P. M. on the 1st, and 6:30 on the 31st. He is steadily approaching the earth, and by the end of the month is less than fifty million miles distant, which makes him appear very bright.

Jupiter is evening star at the beginning of the month, setting about 7 P. M., and too near the sun to be easily seen. As he passes through conjunction on the 23rd, he is practically invisible later in the month. Saturn is in Aries, approaching opposition. He rises before 7 P. M. in the middle of the month, and is well seen before midnight.

Uranus is in quadrature with the sun on the 19th, and can be observed in the west in the early evening. Neptune is in a similar configuration, on the other side of the sun, on the 17th, and is visible in the morning sky.

The moon is full at 11 P. M. on October 7th, in her last quarter at 7 P. M. on the 14th, new at 11 P. M. on the 21st, and in her first quarter at 2 A. M. on the 30th. She is nearest us on the 11th, and farthest away on the 27th. The present new moon is marked by an annular eclipse of the sun, visible along a tract passing from the Aral Sea through Turkestan, Tibet, and southern China, thence through the southern part of the Philippines, and over New Guinea. As a partial eclipse it will be visible over all southern Asia and Australasia from India to Siberia, and from Japan to southern Australia.

Besides the conjunction with Venus on the 18th, already mentioned, the moon passes near Saturn on the 10th, Mars on the 11th, Neptune on the 14th, Mercury on the 21st, Jupiter on the 23rd, and Uranus on the 29th, none of the observable conjunctions being close.

A Goose-neck

ONE of the handiest tools in working around a house or small shop is a goose-neck, such as shown in the accompanying sketch. It is practically a small crowbar, pointed at one end to form a pinch bar and returned at the other end to form a claw which can be used for

A goose-neck.

pulling nails or small spikes. It is easily made, inexpensive, can be used in many ways and will be found especially useful in moving stones or other heavy objects, prying timbers apart, opening boxes, wrecking small buildings and in a hundred other ways in which a small, easily handled crowbar can be used to advantage.

A New Range Finder

THE accompanying illustrations convey a very fair idea of the appearance of the Barr and Stroud range finder, at present used in the British army and now undergoing a series of tests by officers of the United States army, stationed at Fort Sam Houston, Texas, with the view of determining what advantages, if any, it possesses over the Weldon instrument as used by our own government.

The principal claims of superiority of the Barr-Stroud finder over other instruments of similar nature are its portability, absence of all delicate mechanism, ease of manipulation and the fact that it obviates all necessity of the services of more than one man to establish a measured base.

The invention of the range finder was the outcome of a public advertisement, issued by the British War Office in 1888, for an instrument which would fulfill certain specified conditions.

In the working out of the design for the finder it was sought to make the accuracy of the instrument, so far as possible, independent of the precision of such mechanical parts as micrometer screws or any delicate mechanism which might become worn or deranged through hard continued service. This has been accomplished by the employment of a graduated deflecting prism to which the scale is directly attached.

As originally produced, however, the range finder fell far short of fulfilling expectations, due principally to the difficulty of making the optical parts, which are of exceedingly novel design. It was only within the past few years, when the quality of optical glass procurable had reached such a state of perfection, that the instrument was accepted.

In construction, the range finder consists of two telescopes of twelve powers each incorporated in a common tube, aggregating over two inches in diameter, leather covered and closed at both ends.

The light through each telescope is admitted through a square-shaped aperture near each end of the barrel, the lenses contained therein being protected from dust and other injury by a steel sleeve covering over the aperture. The light admitted through these apertures is directed [illegible] of reflectors along the inside of the tube to the eyepieces.

The whole arrangement is such that the combined telescopes may be simultaneously directed on the same target, the range finder forming the base of the triangle, having at its vertex the object, the range of which is determined by measuring the parallax.

The operation is exceedingly simple. To make an observation the observer grasps the handles and directs the instrument toward the object whose distance is to be ascertained, holding the range finder horizontal with the line of object.

In the right eye-piece are placed two mirrors separated by an extremely narrow horizontal line. Supposing the object selected is a flag staff, the picture presented to the observer will be that of a broken column the upper part of which has been moved to the left

In the case of looking at a tall building, the picture shown resembles nothing more than one brick overlapping another.

This distortion is due to the lack of coincident focus between the two telescopes; that portion of the image shown in the upper half of the field having been formed by the left hand telescope, while the lower portion of the image is formed by the right hand telescope.

The next procedure is to bring these broken lines into plumb, which is accomplished by means of a large screw having a milled head placed near the tripod head and so situated that it may easily be manipulated by the thumb and forefinger of the right hand while grasping the handle. This screw, when turned to the right, causes the upper half of the image to move to the left and its parts to separate; when the screw is turned to the left the two halves of the image are brought together, so that the perpendicular lines coincide at the dividing horizontal line and all distortion disappears.

When this is done the correct distance may be read through the left eye-piece, where a series of figures in yards appear on the surface of a wide disk, the scale having moved according to the direction in which the operating screw head was turned.

It will be seen therefore that the correct range always depends upon bringing the two halves of the image into exact alignment at the line separating the two mirrors

The advantages claimed for the finder are:

First. Only one observer required

Second The range of moving objects can be continuously observed

Third. It is not essential in the types suitable for infantry and cavalry that the instrument be level when taking observations.

Fourth. It can be used at night to take the range of distant lights.

Fifth. Rapidity of operation—30 seconds or less being all the time required for determining a range.

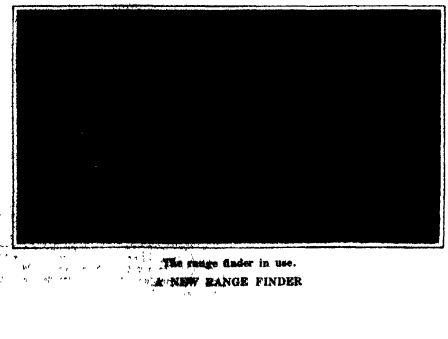
Sixth. It can be used from cover and from a prone position so that the observer's whereabouts are not disclosed to the enemy.

These range finders are made in sizes varying from those having 15 and 12 foot bases, for use on ship board and in sea coast forts, to an instrument with a 4 foot 6 inch base, for field artillery, down to those intended for infantry and cavalry, having bases of only 32 and 26 inches

It is the last and most portable model which may be carried in a case and slung over the shoulders that officers are now experimenting with at Fort Sam Houston

Its length over all is only 30 inches and its weight 7¼ pounds

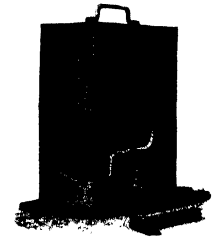
The instrument may be used mounted on a light tripod or it may be used while standing erect with the aid of a light steel rod, the base of which rests in a socket carried in a belt and supported by shoulder braces, or by lying in a prone position upon the ground



The claims as to ease of manipulation coupled with accuracy appear to be well founded. Upon one day of the tests a civilian spectator was asked to find the range of a building, distant nearly three miles. Within about 15 seconds he announced a result, which was only 140 feet out of the way, according to the calculations made by Col Brown himself Another spectator, measuring the distance across the parade grounds to the barracks, gave the correct reading (392 yards) at the first attempt.

Mounted on a tripod.

Supported from a belt at the waist.



The range finder in use.

A NEW RANGE FINDER

A Gasoline Tank and Pump for Automobilists

MANY automobile users install gasoline tanks with pumps, in their yards, adjacent to their private garages. In some places the local fire regulations require that the tanks, when installed be located a given number of feet from any building The writer's attention was called to a cover and guard for the pumping devices of such a tank which protects the pump and prevents any unauthorized person from tampering with it It consists of a box open at the bottom and of such size and shape

A gasoline tank and pump for automobilists

as to fit over the pump Near the bottom of the box are two opposite slots, *A*, reinforced by metal plates *B* and a bolt *C*, with a head at one end an opening near its other end is passed through the slots *A* and secured by a padlock. This bolt *C* passes when the box is fitted over the pump below a bar *E* which extends between the filling pipe *F* and the dispensing or pump pipe *G* of pumps of the Bowser type, and so locks the guard box over the pump The box, such as shown, has been in actual use for several months and has proven satisfactory in every respect

Notes for Inventors

Cloth Pinions—Cloth pinions are highly successful devices for reducing the noise and increasing the life of power transmission gearing. Metallic gearing, especially steel, is always more or less noisy in operation, the noise becoming particularly troublesome in the case of high speed gear trains Furthermore iron or brass gearing has not sufficient elasticity to successfully withstand the shocks or back lash caused by the torque variations incident to the operation of machine tools such as punches, shears, planers, etc In order to overcome these drawbacks, various kinds of non-metallic substances such as rawhide and paper, have been used instead of brass and cast iron for one or more members of gear trains, but the results have been only partially successful As a rule pinions made of such substances were not sufficiently impervious to moisture or unaffected by exposure to heat, and in the case of rawhide were liable to injury by rats and mice when kept in stock In the cloth pinions developed by a prominent electric company, these defects are entirely eliminated, both by the nature of the material and the method of construction employed The blanks from which the pinions are cut consist of a filler of cotton or similar material confined, at a pressure of several tons to the square inch, between steel "shrouds" or side plates the whole structure being held together by means of rivets, or, in case of very small pinions, by threaded sleeves After the teeth are cut, the cloth filler is impregnated with oil. Cloth pinions are entirely impervious to moisture, unaffected by changes in atmospheric conditions and absolutely vermin proof. Cloth pinions have a wide range of application They are particularly suitable for use on the shafts of back

geared motors employed for driving lathes, planers, drill presses, shears, punches, and other machine tools, for loom and spinning frame drive in cotton, silk, worsted, carpet, and textile mills in general, for operating pulp and paper mill machinery, for driving printing presses, and for the valve, ignition and timing gear trains of automobile and other types of internal combustion engine.

The Deplorable Fertility of the American Inventor.—At a recent meeting of the National Electric Supply Jobbers, an address was made by one of the members, deploring the fertility of the American inventor, which, it is claimed, makes material antiquated before it can be disposed of by sale It is necessary to purchase material in quantities in order to get much of a profit, but before this can be disposed of there are new devices and features on the market which are preferred to earlier patterns Why not devise a new selling system instead of damning the inventor? Perhaps some thoughtful inventor will help this human back-number out

Another Lamp Filament Patent.—Carl Auer von Welsbach has just secured a patent on the manufacture of electric lamp filaments The process provides for eliminating the gases occluded in filament containing a metallic oxid and osmium by slowly bringing the filament up to a temperature sufficient to drive off the gases, but below the reduction temperature of the oxid, and finally increasing the temperature to white incandescence, and partially reducing the oxid

Recent Reissues.—On August 15th, 1911, four reissue patents were granted. In all four cases the reissues issued to assignees and the assignee in each case is a corporation

Battle Creek Patent Foods.—Three patents, No 1,001,044, 1,001,045, 1,001,149, for food compounds, and one patent, No. 1,001,050, for a food product, have been issued to Dr. John H. Kellogg of Battle Creek, Mich. The compound of the first patent includes gluten, legumes and yeast products, while the second substitutes nuts for the legumes, the compound in each case being cooked into a homogeneous mixture of fibrous consistency and meat-like flavor The compound in patent No 1,001,149 includes gluten, potato and yeast products, while the patent 1,001,050 combines casein, gluten, oil and a yeast product, the mixture in each case having a meat-like flavor

Another Ozone Patent.—The distribution of ozone is the object of an apparatus patented, No 1,001,038, to Frederic Georg Jaisch of Rheydt, Germany, assignor to Otto von Mühlmann of Brussels The apparatus comprises an ozonizer with a discharge conduit opening in front of the blades of a fan, with a funnel-shaped screen between the blades and the discharge conduit, a second screen being fitted to and spaced from the first screen and the conduit opening into the space between the screens

Blowing Bad Breath Away From the Dentist A dental appliance, providing means whereby a flat blast of air will be delivered between the face of the patient and that of the operator, thereby preventing each from inhaling the other's breath, has been patented, No 1,001,362, to Charles W. Davidson of Jefferson City, Mo

A Woman Inventor.—Women frequently invent devices for domestic use This is true in the case of Mary M Clarke of Des Moines, Iowa, who has secured a patent, No. 1,000,073, for a fish-scaling tool which has a handled scraper with a reticulated or wire screen guard extending in both directions beyond the scraper, the latter being shown as formed with a number of serrated scraping blades.

Col. Krag in America.—Col. Krag of Norway, inventor of the celebrated Krag rifle, is making an extended visit to this country and called at the Patent Office in Washington and was shown the interesting features of that branch of the government. The great inventor is a man apparently in the sixties, well preserved, and is greatly delighted with the courtesy and the hospitalities which have been extended to him.

The Government Advertises a Patent.—It is not often that a government publication exploits and advertises the sale of a patent, but a recent government publication, after describing an invention somewhat in detail, concludes with the following paragraph "The inventor is on the point of selling his French rights in the invention, and application has been made for a United States patent The experiments were witnessed by the editors of the three Havre daily newspapers, several members of the municipal council, and other authorities who signed a certificate of proof. A sample of the new will be loaned to interested firms which apply to the (giving here the name of the government office)."

Synchronously Operated Musical Instruments.—Samuel S Waters of Washington, D. C., has patented, No. 1,002,100, means for synchronously operating two musical instruments, in which a movable record for one instrument moves a member at a proportional speed and the record for the other instrument is caused by said member to move at all times at a speed proportional to the speed of the record of the first machine The patent is assigned to the Aeolian Company of New York city.

A Stand for Assembling Automobiles.—A stand for assembling vehicles, such as automobiles, has been patented, No 1,001,-619, to Howard E Coffin of Detroit, Mich., and includes means for supporting the axles and the main elements of the frame separately and in their normal relative positions and means for lowering the support to disengage it from the assembled vehicle to rest the latter on its wheels so the vehicle, when assembled, can move off on its own wheels.

General Electric Company Patents.—Among the patents issued August 29th, 1911, are eleven issued to the General Electric Company, the inventors including Elihu Thomson, Conrad Baumgardner, Fred B Corey, Allen A Tirrill, Howard E. Sargent and Kennett F Kingwell.

A New Pavement.—We do not always realize that the pavements we walk or ride on may be patented A patent, No. 1,001,-695, to August E. Schutte of Newton, Mass., is for a pavement consisting of a layer composed of stone, coated and cemented together with relatively pure Portland cement, with the spaces between the coated stones filled with bituminous cement.

A Gas-driven Locomotive.—In a locomotive patented, No. 1,001,703, by Arnold Stucki of Allegheny, Penna., is provided a suitable unit frame, carried by the locomotive wheels, and this frame is provided with a continuous gas-producing apparatus and with an internal combustion engine, connected with the producer, adapted to drive the locomotive wheels. An air pump is also carried by the unit frame and is adapted to start the engine.

A Queer Coffee Pot.—In patent No. 1,002,819, to Franklin V. Brooks of New York city, is shown a coffee-making device in which a coffee pot and a boiler, side by side, are pivoted so they can swing to bring one or the other over a heating lamp. The boiler is held over the lamp until the water is transferred from the boiler to the coffee pot, when the weight of the water will operate automatically to swing the coffee pot to a position over the lamp.

A New Kind of Box Kite.—Patent No. 1,003,062 has been issued to Albert O. Paulson of Los Angeles, Cal., for an air ship characterized by a pair of box kites fore and aft and connected together and mounted with an edge at the top and bottom and having the lower corners cut away to admit air. Horizontal sustaining surfaces are provided on each kite.

Making Flour by Steam.—A new process of making flour or meal is presented in the patent, No. 1,002,990, to Charles Herendeen of Chicago, in which steam is injected into a mass of cereal to disrupt the starch cells, after which the mass is dried by passing it through blasts of air, and is then ground into flour or meal of any fineness.

A Novel Amusement Device.—William C Sanford of Kent, Wash., has patented, No. 1,002,874, an amusement device in the form of a transparent barrel having a visible outlet, and an invisible outlet by which the receptacle may be emptied while the visible outlet is closed. The barrel is suspended by a number of lines and one of the lines is hollow and connects at one end with the invisible outlet, while its other end leads to a suction pump, placed out of sight, and which can be operated to pump the contents of the barrel.

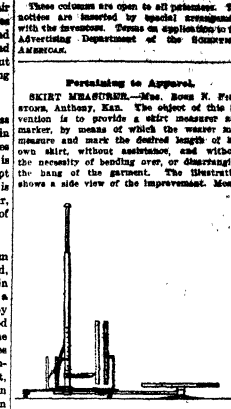
An Automatic Pile Cleaner.—For protecting piles, Charles N. Hubbard of Anacortes, Wash., provides in a patent, No 1,002,847, a float, surrounding the pile so it will rise and fall with the tide, and a brush is connected with the float so it will move along and brush the pile as the float moves up and down. A quantity of a suitable preservative is carried by the float and conducted by pipes to the brush so it can be distributed to the surface of the pile

A New Twist Drill.—The Hoefer Manufacturing Company of Freeport, Ill., as assignee of Frederick W. Hoefer, has secured a patent, No 1,002,846, for a twist drill whose shank is twisted alternately in opposite directions, the shank being so twisted from a flat bar.

Legal Notes

Conflict Between Commissioner's Decision and Bill in Equity.—The Assistant Commissioner of Patents, Mr Tennant, has decided in the case of McIntyre v. Perry that where, after a decision on priority by the Court of Appeals of the District of Columbia, the defeated party files a bill in equity under the provisions of section 4915 Revised Statutes, the filing of such bill does not operate as a *supersedeas* of the judgment and that the issuance of the patent to the party who succeeded before the Court of Appeals cannot be suspended pending the final determination of the suit.

Invention Completed in a Foreign Country.—In affirming the decision of the Commissioner of Patents in the case of De Kando v. Armstrong, the Court of Appeals of the District of Columbia has decided that where a party completed the invention in issue in a foreign country and knowledge of such invention was brought into this country and disclosed to others, the foreign inventor can derive no benefit from the work done in such foreign country and the disclosure of the invention to others in this country is not equivalent to a reduction to practice of the invention, but is merely evidence of conception thereof. In concluding his decision, Mr. Justice Van Orsdel says:



"The right of appellee to a patent cannot be superseded by any act of appellant's short of a reduction to practice prior to appellee's filing date Had his foreign invention been reduced to practice here prior to that date, appellee's conceded lack of diligence would have been sufficient to have entitled appellant to the award of priority, but, inasmuch as, in reduction to practice abroad cannot be considered, appellee must be regarded as the prior inventor."

RECENTLY PATENTED INVENTIONS.

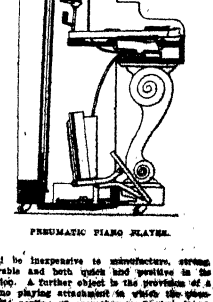
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

SKIRT MEASURER.—Mrs. Rosa N. Fenstrom, Anthony, Kan. The object of this invention is to provide a skirt measurer and marker, by means of which the wearer may measure and mark the desired length of her own skirt, without assistance, and without the necessity of bending over, or disarranging the hang of the garment. The illustration shows a side view of the improvement. Means

SKIRT MEASURER.

provide for the skirt being brought against the marking material which results in the making of a transverse mark on the skirt. The skirt is brought back to first position and the wearer then revolves the platform the desired distance, and makes another mark on the skirt. This process continues until the measuring and marking is completed.



Of Interest to Farmers.

BUTTER AND MILK MIXER.—C T. Rayton, Buffalo, N. Y. In operation a quantity of butter and milk is first placed in the body of the apparatus, the proportions being preferably a pint of milk to a pound of butter, and the dasher is then operated for the purpose of cutting up the butter and working them together, so as to merge them and form practically one substance, or a butter compound which becomes solid the same as butter proper

Of General Interest.

FERTILIZING SCALE POISON.—W B Kleckner, Bay City, Mich. This poison destroys all kinds of parasitical insects infesting various parts of fruit, forest and ornamental trees or shrubs and vines, and, further, operates to discharge food products directly into the sap, supplying an immediate stimulation and fertilization of all tissues and growing parts of trees, quickly correcting the failing activity and low vitality caused by the ravages of parasitical insects or by depleted and unsatisfactory soils

PNEUMATIC PIANO PLAYER.—William G MacArthur, 428 E. 149th St., New York, N. Y. This invention relates to an improved piano-player, an accompanying illustration of which shows it in a vertical section through a piano with the attachment thereon. An object of the invention is to provide a device which

PNEUMATIC PIANO PLAYER.

will be inexpensive to manufacture, strong, durable and both quick and positive in its action. A further object is the provision of a piano playing attachment in which the pneumatic portion of operating mechanism is positioned directly to the keys, thereby a great saving in space and more positive and sensitive movement is obtained.

PICKLING OF PICKLING.—A. SAGMANN, New York, N. Y. This process is for use in making edible and easily digestible acid pickles from green cucumbers, in a simple and economical manner, and reducing the loss of pickles, that usually become tainted and soft, to a minimum. The process subjects green cucumbers to the action of dilute boiling acid solutions of common salt, chemically pure hydrochloric acid and soda bicarbonate.

PILE PROTECTOR.—C. N. HUBBARD, Anacortes, Wash. The particular object of this device over that shown in the former patent granted to Mr. Hubbard, is to provide a pile protector so constructed that the chemical compound used in protecting the pile may be carried to a greater depth than ever before, whereby the extermination of teredo and limnoria and other marine worms is facilitated.

STAMP HANDLING DEVICE.—R W. JONES, Lincoln, Neb. This improvement has reference more particularly to a device comprising a casing constituting a magazine for the stamps, a guide member associated with the magazine and adapted to have the stamps passed along it manually, from the casing to the point of application of the stamps, and a moistening device for wetting the adhesive of the stamps before they are applied.

TRAP.—T. H. TAYLOR, Luserne, N Y The intention here is to provide a trap for trapping animals. Use is made of a fixed toothed jaw constituting a base, a swinging jaw mounted on the toothed jaw, a tripping rod for engagement with the swinging jaw, and a tripping plate on the fixed jaw and adapted to be releasably engaged by the tripping rod.

COUPLING FOR REINFORCED CONCRETE PIPES.—C. H. WILSON, Red Oak, Iowa. An object of this inventor is to provide a means for uniting two pipe sections of various lengths in a manner that there will be a positive and tight joint between the different sections, and it has for a further object the disposition of this coupling means so that they are not exposed to the weather and are thereby protected from any rusting action.

FORM FOR PRODUCING ARTIFICIAL TOOTH CROWNS.—E. R STEVENSON, Oakland, Ore. In this case the improved tooth form being hollow is adapted to receive a plug or other device adapted for expanding it, and thus, by using different sized plugs or expanding devices, the form may be enlarged circumferentially so that several sizes of crowns may be produced by means of one form, and also the shape of the form may be changed to a certain extent, by using plugs differing more or less in contour.

BAKER'S OVEN ATTACHMENT.—R. L. GILLESPIE, New York, N. Y. In this instance the improvement pertains to an attachment for a baker's oven, in the form of an inlet, whereby access may be had to the interior of the oven in a most convenient and readily accessible manner by means which can be readily controlled, and which will be simple and inexpensive.

GUN LICENSE CERTIFICATE HOLDER.—O R. DUNCAN, Jefferson, Iowa. The purpose here is to provide a license certificate holding receptacle which is to be attached so that the hunter may be certain to have the license certificate with him every time he takes his gun to go hunting The receptacle is attached to the barrel by a clamp having arms which are curved and are disposed against the outer side of the barrel or barrels, the clamp arms being held against the gun barrels by a screw member.

ATTACHMENT FOR TRIAL FRAMES.—G. A. GRIFFIN, New York, N. Y. The aim here is to furnish an attachment for supporting a smaller lens substantially parallel to the trial lenses and adjacent the lower portion thereof, so that the eyes may be tested both for long distance and for reading at the same time, and the patient may know the advantages and operation of using a bifocal lens rather than having separate pairs of eyeglasses or spectacles for general use and for reading.

Hardware and Tools.

PICK.—J. E CARTER, Reno, Nevada. Among the principal objects which this present invention has in view are:—To provide a construction and arrangement of a pick to facilitate the replacement of steel points, and to provide a construction and arrangement which renders possible the carriage of a supply of renewing pick points adapted for attachment to the pick body or eye.

MITER BOX.—J. G. WORTHAM, Tullahoma, Tenn. This box consists of a bed, which may be widened or narrowed to conform with the dimensions of the work, a swinging arm supporting and carrying the saw guide, and capable of being lengthened and shortened, to correspond with the positions of the bed sections, and an adjustable bed, together with a scale for indicating angles assumed by the arm.

DUST PREVENTER FOR STONEWORKING TOOLS.—W. M. HOLDEN and E. M. TUBIN Barre, Vt. To avoid several objections this invention is devised, and consists of a fluid discharge pipe having an extended atomizing puller, and a liquid supply member arranged to discharge on the said outlet, the above pipe communicating from the exhaust of the tube, with the extended atomizing outlet of liquid flow.

PENCIL HOLDER.—A. B. COFFIN, Apache, Okla. Among the principal objects which the present invention has in view are: to provide a simple, economical and efficient form of pencil holder for pencils, fountain pens and articles of a similar character; and to provide a holder light in construction and adapted for easy attachment to the clothing of the user.

LOCK.—Y. Q. CALDWELL, Paris, Tenn. Although the form of this device is that of a padlock, it may be utilized in other forms of locks such as trunk locks, or similar devices. An object of this invention is to provide a device strong and durable, because it consists of relatively few parts Owing to its peculiar construction it is difficult to pick, and the parts may be easily assembled or disassembled

HASP LOCK.—Y. Q. CALDWELL, Paris, Tenn An object of this improvement is the provision of a combined lock and hasp, which does away with the necessity of the use of a padlock or other means for securing the hasp to the staple. It is in the simplicity of the lock and the elimination of a multiplicity of parts that the merit of this invention lies, as well as in the fact that these few parts are strong and durable and are not liable to get out of order.

Heating and Lighting.

JOINT AND COUPLING.—B W STOUFFER, Pittsburgh, Pa. This improvement provides a joint and coupling, more especially designed for use as a swing joint, socket joint, coupling or other gas fixture, and arranged to permit of conveniently placing the joint or coupling in position on any desired fixture without the aid of tools and without danger of leakage or the parts becoming accidentally disassembled or separated

Household Utilities.

DUMB-WAITER.—E N HALLETT, Canton, Pa. In this case the invention provides a pantry closet on a dumb-waiter so that when food is placed on the shelves of the closet the dumb-waiter may be lowered through an opening in the floor of the kitchen to the cool air of the cellar. A supporting frame is constructed on the waiter so that when it is lowered with the frame, the working parts are disposed below the floor of the kitchen

VENTILATOR.—W. F GUILMETICH, Merlden, Conn. This invention has for its principal objects to provide a ventilator adapted to be attached to a window and to cause the ingress of air into the interior of a building without causing a draft, at the same time keeping out all objectionable foreign matters and substances, and to provide such a ventilation with means for regulating the influx of air to the desired extent

Machines and Mechanical Devices.

WAVE MOTOR.—A. W DOWE, Camden, N J This invention provides means to avoid the destructive operation of the elements incidental to storms. provides a construction which receives and transmits the full dynamic power of the surf or waves at the shore line; and provides a machine the power or full efficiency of which may be augmented to a large degree by multiplying the motor units indefinitely

HINGE MECHANISM FOR THE COVERS OF LOOSE LEAF BOOKS.—F L. IMPEY, 19 Barwick Street, Birmingham, England This mechanism is for use on leaf books or binders of the type in which the covers are pivotally connected at their rear edges to clamping bars by which the leaves are bound in position, the covers being connected together by leather thongs, which pass through the clamping bars and are tightened or released for securing or liberating the leaves by mechanism arranged within one or both of the covers

WELL DIGGING APPARATUS.—C R MARTIN, Portland, Ore The invention refers to apparatus for digging wells, and for forming bores in the earth, and has reference more particularly to apparatus comprising a casing adapted to be advanced to the core as it is formed, a drill-head associated with the casing and means for conducting fluid pressure to the drill head to cause it to advance into the earth

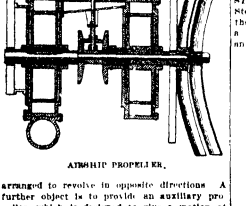
GREASE CUP.—FRANK L. TERREE, care of R S HADLEY, 1806 11th Ave, Altoona, Pa. An object of this invention is to provide a cup for holding hard grease of a semi-fluid nature with means for forcing the grease through a feed opening. A further object is to provide a device which may be readily filled and in which

GREASE CUP.

the cover forms a guide member for the stem of a movable plunger or piston. Again, the aim is to provide a cup of maximum capacity, owing to the fact that part of the mechanism for exerting a pressure on the grease is disposed on the exterior of the cup rather than on the interior The illustration gives a perspective view of the device in operative position

ADVERTISING DEVICE.—H E KIESSIG, Sacramento, Cal The object here is to provide a device for continuously operating that class of advertising devices known as "Chinese puzzles," or "Jacob's ladders," and consisting of a plurality of plates or panels, so connected that when the topmost panel is severed, the other panels will be reversed in succession from above downward

VENDING MACHINE.—C S. HARDY, San Diego, Cal The purpose of the invention is the provision of a device which will dispense accurately measured quantities of liquid, without the necessity of an attendant, and which will be operated by the liquid, under pressure. A further object is to provide a device wherein the amount dispensed may be varied, by varying the capacity of the pump



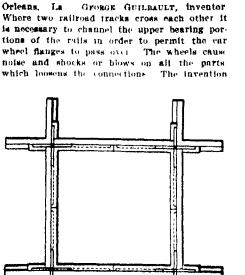
DEVICE FOR ELEVATING WATER, MERCURY, OR OTHER LIQUIDS.—JAMES R HALL, Winnfield, La This invention relates to means for raising water, mercury or other liquids to a higher level It is an improvement over that disclosed in a prior application of Mr Hall. The main object of the present invention is to increase the turning effect by the use of impact wheels instead of troughs, the motion of the wheels being communicated to the revolving frame so as to increase the rotative movement of the latter

MACHINE FOR EXTRACTING ESSENTIAL OILS FROM CITRUS FRUITS.—WALTER A D ALLPORT and THOMAS J W. C DAVENPORT, Roseau, Dominica, British West Indies This invention provides a machine for extracting essential oils from the outer rind of citrus fruits, such as lemons, oranges, limes, etc., and arranged to insure a continuous operation, thus permitting the handling of a large number of fruits in a given time, and insuring complete extraction and gathering of the oil without injury to the fruits

VACUUM STOCK THICKENING AND WASHING MACHINE.—T E WARREN, Ticonderoga, N Y This invention pertains to paper-making machinery The aim is to provide a thickening and machine arranged to separate water from fibrous material without the loss of the finer fibers and other minute particles, to produce a stock of uniform consistency and to permit convenient adjustment for producing a stock of a thicker or a thinner consistency, according to the nature of the fibrous material to be treated

STOP VALVE AND TAP.—J T SHELDON, "Olgate," Fernhill Street, Fernhill, New South Wales, Australia The purpose of the inventor is to provide a simple and effective means of preventing the escape of water, steam or other fluid normally controlled by a valve, when the cover thereof is removed, in order that the internal parts and mechanism may be withdrawn for examination, replacement or repair

AIRSHIP PROPELLER.—HOMER A KING, P. O. Box 474, Colton, Cal. The invention illustrated by the accompanying engraving has for an object the provision of a novel form of propeller having a double set of blades, one set mounted on a rod and the other set mounted on a sleeve carried by the rod, the propellers being oppositely inclined, and being

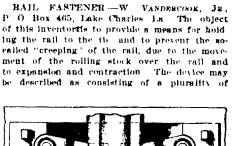


AIRSHIP PROPELLER.

arranged to revolve in opposite directions A further object is to provide an auxiliary propeller, which is designed to give a motion at right angles to the first named propellers Another object is to provide means for operating the propellers simultaneously, and for throwing the auxiliary propeller out of gear when desired

DRESSER FOR BAND SAWS.—F P SMITH, Baypoint, Cal This improvement provides an attachment to the usual grinding machine, the operation of which results in removing the burr at the edge of the face of the teeth, and to reduce the teeth to the same spread; provides means for dressing the sides of the teeth subsequent to grinding, and to accomplish the same automatically, and to shape the sides of the teeth to conform with the set thereof, and provides means for regulating the pitch and spread of the grinding members.

Railways and Their Accessories.

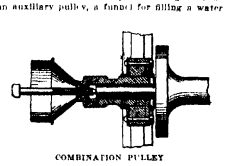


NOISELESS RAILROAD CROSSING.—AL FRED D DANZIGER, 204 Carondelet Street, New Orleans, La GEORGE GUILBAULT, Inventor Where two railroad tracks cross each other it is necessary to channel the upper bearing portions of the rails in order to permit the car wheel flanges to pass over The wheels cause noise and shocks or blows on all the parts which loosens the connections The invention

NOISELESS RAILROAD CROSSING

overcomes these objections by providing each rail adjacent the point of intersection with a pivoted lever, there being a pair of intersecting levers at the intersection of two rails A bell-crank lever is pivoted to each first mentioned lever as in operative relation with a sliding block adapted to engagement with the other intersecting lever whereby the car wheels pass over the top of this lever and do not engage the channels of the rails A railroad cross ing provided with this invention is shown in the illustration

RAIL FASTENER.—W VANDERCOOK, JR., P O Box 465, Lake Charles La The object of this inventor is to provide a means for holding the rail to the tie and to prevent the so-called "creeping" of the rail, due to the movement of the rolling stock over the rail and to expansion and contraction The device may be described as consisting of a plurality of



RAIL FASTENER

pairs of gripping jaws, one member of each pair arranged one on each side of the rail, and operated by the longitudinal movement of the rail The arrangement of rise substantially parallel with the length of the tie, and with the grain of the tie, prevents any lateral movement of the anchor plate and the spikes at the plate corners assist in this as do the center spikes The engraving is a plan view of a portion of the rail provided with the improvement

Pertaining to Vehicles.

COMBINATION PULLEY FUNNEL AND STRIPPING JACK.—TRESHAM F HUTCHINGS, Stone Ford, N Y The principal object which the present invention has in view is to provide a device constructed to permit being used as an auxiliary pully, a funnel for filling a water

COMBINATION PULLEY

or gasoline tank, and means for stripping a tightened wheel from the axle bearing The view shown in the accompanying engraving represents a vertical cross section of an automobile wheel and the axle thereof showing a pulley constructed and arranged in accordance with the present invention as operatively connected therewith When the pulley is not employed, it is removed from the axle and carried as a separate tool in the body of the vehicle It may then be used as a funnel for filling the tanks.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Better Than Nails

After fitting the corners of a picture frame or the joints of other light work, have you ever ruined the whole thing by splitting it with a nail? Then you've had need for

LE PAGE'S GLUE

For, of course, glue won't split the weakest wood. Yet a square inch of glue makes as strong a joint as three six-penny nails do.

And is just as handy as nails or string. Put up in air-tight bottles, it positively cannot dry out. The last bit you scrape from the bottle with the metal spreader is as good as the first.

With the metal spreader you can use glue in places where you couldn't use a brush, and without fuss or waste.

Get a bottle today and put it with the hammer and saw. Send, too, for our booklet—"Gluetism"—Gives 101 uses for glue in our new bottle and patent collapsible pin sealing tube.

NEW BOOKS, ETC.

HANDBUCH FUR HEER UND FLOTTE. Enzyklopädie der Kriegswissenschaften und verwandter Gebiets, herausgegeben von Georg von Alten, Generalleutnant a. D., unter Mitwirkung von mehr als 200 der hervorragendsten Fachautoritäten. Vollständig in 108 Lieferungen reichillustrierten Textes mit farbigen Beilagen, Karten, Plänen, Gefechtsskizzen usw. Deutsches Verlagshaus Bong & Co.

The financial aspects of modern warfare are considered in the present instalments, Nos 34 and 35, of the Handbuch. Excellent tables are published, which show the rise and fall in military expenditures during the last few decades. It is particularly interesting to study the influence which actual warfare has had upon the expenditures. The whole article is a warning against thoughtless comparisons. Inasmuch as all statistics are based upon different facts. In the article on the French army, a very complete and accurate description will be found of the geography of France in its relation to French military affairs, French railways and fortresses, French cable and telegraph lines, and the history of the French army. The discussion of the army itself begins with an excellent review of its development from the days of Louis XIV, and concludes with an exhaustive description of its present status. It enumerates the difficulties that beset the commanding officers, and shows on the basis of numerous tables, the composition of the peace and war footings, the organisation of the naval arm of the service, the military budget and character of the uniforms. French naval and colonial affairs are treated in the same manner. Flying machines also find a place in these two instalments, treated, of course, from a military standpoint.

SEEING EUROPE BY AUTOMOBILE By Lee Meriwether New York The Baker & Taylor Company, 1910 12mo; 415 pp Price, $2 net.

The author once wrote a book on how to see Europe on fifty cents a day, but he has evidently been blessed with a change of fortune in the last quarter century, for now he travels in a two-seated, four-cylinder 24 horse-power roadster, but the passion for travelling cheaply has been far from being quenched by comparative affluence. The author details with great precision the distances traveled and the things seen. It is an instructive book for all those who are thinking of taking the trip. There is an excellent map in the back. It is well illustrated.

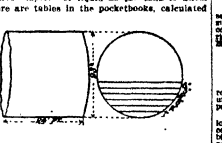
CHARACTERISTICS OF EXISTING GLACIERS By William Herbert Hobbs, Professor of Geology in the University of Michigan New York The Macmillan Company, 1911 8vo, 301 pp, illustrated Price, $3.25 net

Prof Hobbs discusses his subject under three heads, mountain glaciers, Arctic glaciers, and Antarctic glaciers. He points out that a mistake is made in treating of glaciers as if all were governed by the same laws. He prefers rather to emphasize the fact that the laws governing their nourishment and depletion are far from identical. The division is broadly made between those glaciers which cover completely a large portion of rock surface, having the form of a shield or flat dome, and the remaining types which may be designated as mountain glaciers. Small ice caps occupy an intermediate and transitional position between these two types. The language and treatment is rather technical, but well repay the slight study necessary for the layman to understand its terms. Since, as we are reminded by Sir Charles Lyell, "The present is the key to the past," the study of glacial conditions never fails to create enthusiasm and broaden the understanding.

THE SCIENCE OF CURRENCY AND CENTRALIZED BANKING By Herbert D Miles New York Rand-McNally Press, 1911. 16mo; 47 pp

The author is an ardent champion of the Aldrich plan, which he designates as a work of genius, profound, far-reaching, yet simple and sincere. He reviews the banking systems of the world, compares and contrasts the European credit instruments and discounts with those of the United States, and proceeds to an examination of American methods, their relation to gold reserves and their efficiency in crises. The treatise exhibits some clear thinking and much subtlety of condensation. It aims to give the gist of what has recently been issued by the National Monetary Commission through its various published papers.

CONCRETE MONUMENTS, MAUSOLEUMS, AND BURIAL VAULTS By A A. Houghton. New York The Norman W. Henley Publishing Company, 1911. 65 pp. Price, 50 cents.



Among the new industries opened up by concrete, that of monumental work offers a large and profitable field. No 6 of the "Concrete Worker's" series goes at length into the construction of monuments, mausoleums, and burial vaults, citing their points of advantage and giving the plainest directions for their construction. The illustrations include a variety of artistic designs.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about each matters as patents subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12546) F. B. T. says: A short time ago I bought a barometer, which appears to be a very good instrument, but its action is a little puzzling, and I wonder if you can give me a helpful suggestion. The only fine that the barometer has gone up to 30 was during the extremely wet weather we had a few days ago; and in the dry season which we experienced during the summer, it ranged around 29½ or thereabout. It has never gone much below 29 in spite of the fact that we have had some very heavy storms. I notice in the daily paper that the government barometer at the Springfield armory seems to agree fairly well with mine in its reading, but in that case, it would seem to me that the lettering, which I have noted, is very misleading. I had the impression that a low barometer meant stormy, bad weather and a high barometer fair, dry weather. I would be glad to have you give me any suggestions, either through your paper, for which I am a regular subscriber, or by mail, as you may prefer. A The words Stormy, Rain, Change, Fair, Very Dry, have no meaning whatsoever upon a barometer, and it is very strange that they should be still placed there, since every maker of instruments knows that they are without meaning. The figures around the circles are inches of mercury. In good weather at the sea level the barometer will be found to indicate about 30 inches. A falling barometer indicates the approach of a storm, a rising barometer indicates the approach of continuance of good weather. A high barometer indicates the continuance of the present state of the weather, good or bad. A rapid rise or fall indicates high winds. If you live about 500 feet above sea level, the barometer will be one inch lower than it is at the same time at sea level, and at 1,050 feet above sea level the barometer will be two inches lower than at sea level at the same time. If your barometer does not agree quite closely with the government instrument in the same neighborhood, it is probably out of order and should be tested. The high school in your city doubtless has a good barometer, and the teacher of physics there will be very willing to give you his assistance and advice in the matter. A barometer may be expected to change two inches or thereabout in centers of weather. The best test for a barometer is to hang it by the side of a reliable barometer and compare the reading of the two for some weeks.

(12547) R N M says: Would you please give me a rule or formula for finding the capacity of a cylindrical tank when lying on its side for each inch of the diameter? I desire to make a gage so it can be read at a glance, giving the number of gallons by each inch. The tank is 24 feet long and 93 inches in diameter, with rounded ends, but for our purpose these ends can be considered as square with the diameter. A There is no simple formula for the volume of the successive "layers" of liquid as the tank is filled. There are tables in the pocketbooks, calculated

from the mathematical formulas, which give the area of segments in terms of theorem of the circle. The volume of your tank, 93 inches diameter, 288 inches long, is

$$\frac{93 \times 93 \times 0.7854 \times 288}{231} = 8{,}470 \text{ gallons.}$$

Now, to find the depth to which 100 gallons will fill the tank, we must find the height

$$\frac{100}{8470}$$

of a segment —— of the area of the whole

93-inch circle, or 0.0118 × area of circle. From a table of circular areas and segments (see Kent's "Mechanical Engineer's Pocketbook") we find that a segment having an area of 0.0118 times the area of the circle, would in a circle of 1-inch radius, or 2.14 inches area, have an area of 0.0118 × 3.14, or 0.037 inch, and a height of 0.073 inch. In a 93-inch circle the height of the segment would be 0.073 × 93, or 6.78 inches; so that filling your tank to 6.78 inches depth will measure 100 gallons. Similarly, you can calculate (with the aid of the table) the heights for 150, 200, and all other numbers of gallons, and make your scale accordingly.

LEGAL NOTICES

PATENTS

Trade-Marks
Copyrights &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., as regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Classified Advertisements

Advertising in this column is 1c. each a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

BUSINESS OPPORTUNITIES.

YOUR FACTORY AT TULSA will supply the Middle West, Southwest and Pacific Coast. Rent for room, light, power and heat $1,000 a year. Natural oil and coal within 10 miles. Open river. Four trunk railways. Many firms thriving. Residence already. For further particulars write Secretary, Bureau of Immigration, Tulsa, Oklahoma.

GOOD BUSINESS OPPORTUNITY.—For sale, a well established business, manufacturing and selling a specialty rapidly coming into general use. A good, quick, paying proposition. Address Box 773, or apply confidentially. No special manufacturing experience necessary. Good reasons for selling. Will be pleased to be reviewed. This is an exceptional opportunity for any one having the cash required. Address Pennsylvania, Box 773 New York.

PATENTS FOR SALE

FOR SALE—A patent with cash capital of $10,000. A wood bender. Patent covers all members of bicycle frame, handlebars, spokes. Patent Knife, patentee, Amelia Road, Hartford, Conn.

HELP WANTED.

WANTED—A man or woman to act as our information reporter and to solicit subscriptions for a well-known magazine. Salary $60 to $90 per month. Working to start. Experience not necessary. Address Association, Box 773, Indianapolis, Indiana.

LOCAL REPRESENTATIVES WANTED.—Splendid income assured right man. We will teach you thoroughly after learning our business thoroughly by mail. Former experience unnecessary. All we want is honesty, ability, ambition and willingness to learn a lucrative business. We furnish you the capital to start. This is a rare opportunity for a man in your section to act as our representative. Write for full particulars at once. Address Box 24, Marshall, Mich. The Thomas Manufacturing Company, 1-39 Morden Building, Washington, D. C.

WANTED.

WANTED—One first-class marine engineer and boiler maker; also one man to run planer. Only experienced men will be hired for the above position October 15. For further information address Atlantic Coast Line Railroad, Charleston S. C.

WANTED, to buy 600 pastel with which to purchase several monophones of a well-known French make and start an agency for same. Address Pastel, Scientific American Office, 361 Broadway, New York City.

WANTED—Second hand aeroplane motor. 7 ft. 6 in. front end screw. Address Aeroplane Motor, P. O. Box 1841 42nd Street, New York.

MISCELLANEOUS.

INVENTORS.—We want an article of merit, novelty. Must be cheaply manufactured, handy to utility or novelty protected. Address with terms and particulars, Hercules Co., 211 Bertha B., Pittsburg, Pa.

MOTORCYCLES CHEAP.—Send day for free catalog of new and used motorcycles. Also photographs of speedways and pictures of our outfits for converting bicycles into motorcycles. Shaw Manufacturing Company, Dept. M, Galesburg, Kans.

DIAMOND Scissor is the newest way to grind lawnmower knives. Can save you $10 a year. Will last 25 to 50 yrs. Will buy all grades. Shows anywhere. Experience your spare time. Write for terms and outfit. Your territory limited, write for today. T. M. Stetson, 362 Wayne Street, Jamestown, N. Y.

MAKE BIG MONEY operating a Portable Post Card Machine. Photographs of your home, friends, etc., developed on the spot in ten minutes in the open air or in your home bedroom at night. Does not require an expert photographer to make good pictures. Complete outfit, including supplies, $150. Write today for free booklet. Portable Post Card Co., 1133 Broadway, New York City.

PRIZE—INVENTING FOR PROFIT" Magazine, found only at newsstands. Will mail you copy free. Write absolutely free. Before you patent your invention—see it. Before you sell it, know its value. Before you manufacture it, find out if there is a ready market for it. Before you let a concern have your invention on royalty, know what royalty to ask. Before you decide to form a company, know how to form it and how to finance it. Before you do anything about your invention, get the right information. Address Publisher, 624 F St., Washington, D. C.

INQUIRY COLUMN

Inventors Bureau.—Wanted, by over a million readers of the Scientific American, inventions to sell or manufacture on royalty. Send for free booklet telling how to dispose of your invention. Scientific American Inventors Bureau, 361 Broadway, New York City.

The Current Supplement

THERE economy is used, not on a mere policy of doing things cheaply, but on a systematic and scientific plan of controlling value received against price paid. How the Pennsylvania Railroad guards against loss by poor materials is told us in a valuable article in the current issue of the Supplement.—Prof. Turner's article on The Great Star Map reaches its sixth instalment. Balloonists have observed that to them the surface of the earth appears bowl-shaped. The cause of this is explained by Dr. Charles Forbes of Columbia University.—The sewage purification industry is far from having become standardized. A new apparatus which has been found to give much satisfaction is described by our Berlin correspondent.—In a very excellent article Mr. A. J. Jarman gives practical instructions for the amateur, which will enable him to prepare and mount photographs upon watch lids and the like.—The farmer will find in this number useful information regarding the construction of concrete silos. In these days of remarkable technical development and substitution of all sorts of artificial products for the natural, it is refreshing to note occasionally that for some particular purpose some simple product of nature is still found indispensable. The use of spiders' threads in optical instruments is discussed by W. F. Rigge, who tells us how, on a certain occasion, an entire department of Creighton University Observatory was put out of commission for want of a spider's thread.—Many are the attempts made by amateurs to solve certain mathematical problems, such as the trisection of the angle. It is unfortunate that much ingenuity should be wasted upon such efforts, and discussion of this topic by N. P. Dupuis, should prove very beneficial in clearing up an unfortunate misunderstanding. The problems as ordinarily stated are incapable of solution, not because of any intrinsic bar to such solution, but because of the artificial restrictions imposed by the injunction that the problem shall be solved entirely by Euclidian methods. Remove this restriction and the problems can be solved without difficulty. Insist on this restriction and it can be proved that the problem is incapable of solution.—The influence of the mercury vapor lamp upon the eye is discussed in a note by Dr. W. H. Williams.—We think of surgery as a destructive measure, which may remedy an ill by removing a part of the body which nature intended to be retained. Some of the newest developments bear the promise of constructive work, in which a deficient organ is replaced by a healthy one derived from some external organism. This subject is discussed in an article derived from *La Nature*.—Some interesting new light has recently been shed upon the process of fertilization by researches on the influence of radium upon the frog embryo. A short account of this work is given in the current issue.—From the fertile mind of Svante Arrhenius we have an article on the Fate of the Planets.

The Disposition of Guns in the Dreadnoughts

(Concluded from page 318.)

The second turret from forward is superposed, as is also the second from the stern, the object in each case being to increase the volume of fire along the line of the keel. The fourth turret from aft is also superposed above the third, but here the saving of length was the object in view, as these guns do not bear aft. (Fig. 12.)

The only other six-turret "Dreadnoughts" with a 100 per cent broadside are the Argentine ships "Moreno" and "Rivadavia." These vessels, with twelve 12-inch guns, have four turrets on the middle line and two echeloned (Fig. 13). There has been, and probably will continue to be, much controversy as to which is the more effective arrangement; but the fact remains that the "Wyoming" can cover an arc of 95 degrees on either beam with all twelve guns, while in the case of the Argentine ships this is 10 degrees less. For ten guns the respective figures are 130 degrees and 90 degrees, and for eight, 135 degrees and 135 degrees. The Brazilian battleships "Sao Paolo" and "Minas Geraes" have their guns arranged on a similar plan to the Argentine vessels, but the superstructure divides the echeloned turrets, which are therefore not available on both broadsides.

For practical purposes the French battleships "Jean Bart," "Courbet," "France," and "Paris" are similar to the Brazilian, two turrets being mounted forward and aft (with one superposed in each case), and two abreast amidships. (Fig. 12.)

We now come to a striking variation in design. The German battleships "Rheinland," "Posen," "Nassau," and "Westfalen" all have twelve 11-inch guns as their main armament; but they are so disposed in their six turrets that only eight guns bear on the beam. (See Fig. 15.) It was at first thought that this system was due to a misapprehension as to the system of naval tactics which the "Dreadnought" principle involved, but this is hardly borne out by the fact that the arrangement is being strictly adhered to. The "Thüringen," "Helgoland," "Ostfriesland," and "Oldenburg" are armed with twelve 12 2-inch guns apiece; but the distribution remains the same. Although, therefore, these ships carry as many big guns as the "Wyoming," the latter is 50 per cent superior on the broadsides. The German vessels, with their twelve guns, are no better as line-ahead broadside fighters than the "Michigan," the British "Invincibles," or even the 15,500-ton Spanish Espanas—leaving questions of speed and protection out of consideration.

Curiously enough, the Japanese have also adopted this system, at least for their first two all-big-gun ships, the "Kawachi" and "Settsu," for the distribution of the 12-inch guns in these ships is the same as that of the 11-inch and 12.2-inch in the German vessels. The average student of the naval war between Japan and Russia will be hard put to it to find any justification for this subordination of the broadside, and it is more difficult to understand since it has been reliably stated that all the data gleaned by the Japanese were placed at the disposal of the British authorities. The same tactical data could hardly justify the "Orion" (Fig 7) and at the same time excuse the "Kawachi" (Fig 15)

Summarizing these details, it will be found that the total number of heavy guns mounted in the 68 ships of the "Dreadnought" era whose details are known is 723, a total that could not have been attained with fewer than 181 ships of the pre-"Dreadnought" era. The ownership of the guns, as well as certain other details, is shown in the following table:

Countries	Number of Ships.	Details Known of.	Guns Mounted (Inches Caliber)					
			14 Inch		12.5-in.	12-Inch	11-Inch	
			Total.	Broadside.	Total.	Broadside.	Total.	Broadside.
Great Britain	28	27			104	104	252	236
United States	12	10	91	80			100	100
Germany	21	6					48	32
Italy	4	4					61	51
Russia	4	4					48	48
France	4	4					42	42
Spain	3	3					24	24
Argentine	3	3					24	24
Brazil	3	3					24	20
Japan	2	2					24	24
Austria	4	3					24	24
Turkey	3	0						
Chili	2	0						
Totals	100	68	91		104		543	56
Number of guns in three-gun turrets							111	
Number of guns in center-line turrets			90		104		407	90

It will be noted that as the caliber increases so does the desire to place all the guns on the middle line.

A Political Laboratory

A POLITICAL laboratory has been established at Columbia University through the generosity of Patrick F. McGowan, ex-president of the board of aldermen, and will be available at once for the 180 students of politics at the university. Sufficient money has been given by Mr. McGowan to maintain the laboratory for a year, and it is hoped that the city will make an appropriation for its support thereafter. The laboratory will be under the direction of Professor Munro, who has been appointed to the chair of municipal government. Its purpose is to study the practical problems of city government, and to train students for the public service. Professor Munro will have associated with him a number of lecturers, who will be men actively engaged in the practical work of municipal government.

About Remembering

By ELBERT HUBBARD

HENRY DICKSON
American Psychologist and author of Memory Training and Principal Dickson School of Memory, Auditorium Building, Chicago

FOR a long time I have been promising myself to write up my good friend, Mr. Henry Dickson, of Chicago, and I have not forgotten

Mr Dickson is teaching a Science or System, which I believe is of more importance than the entire curriculum of your modern college

MR. DICKSON teaches memory.

Good memory is necessary to all achievement.

I know a man who is a graduate of three colleges. This man is neither bright, interesting nor learned. He's a dunce.

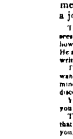
And the reason is that he CAN NOT REMEMBER. He can not memorize a date or a line of poetry. His mind is a sieve.

Education is only what you remember

Every little while I meet a man who has a memory, a TRAINED MEMORY, and he is a joy to my soul.

The manager of a great corporation never misses a face If he sees you once the next time he will call you by name He told me how he did it. He studied memory with Prof Dickson. He said a lot of nice things about Prof. Dickson, that I hesitate to write here lest my good friend Prof. Dickson object.

This Dickson system of memory-training is very simple. If you want to enlarge your arm you exercise it. The same with your mind. You must pay your brain dues in a few easy exercises to discover its capacity You will be surprised how quickly it responds.



You do not know when you will be called upon to tell what you know, and then a trained memory would help you.

To the man or woman whose memory plays tricks I recommend that you write to Prof Dickson, and if his facts do not convince you, you are not to be convinced

ALLEN MFG. CO., 3001 Allen Building, TOLEDO, OHIO

tory for two years. Its purpose is to bring the students in contact with the documentary sources of information, and in addition to place the collection of materials at the disposal of the debating teams of the university.

The laboratory will consist of a select library covering the field of American government and politics. Newspapers from all parts of the country will be kept on file for a certain period and afterward clipped and indexed. A large number of weekly and monthly magazines will be kept on file. Then there will be such books of reference as the American Year Book, the Cyclopædia of American Government, Beard's Digest of Short Ballot Charters, and the like. The laboratory will also contain a large number of federal, state, and municipal publications, which will include the Congressional Directory, Congressional Record, Labor bulletins, consular reports, reports of civil service commissions, the constitutions of all states, legislative manuals, sample ballots, election laws, and, in fact, everything that the student in politics needs Special subjects will also be cared for as well and extensive collections in the field of politics will be made.

A New Opportunity in Industrial Education

THE first requisite of education should be that it helps the boy to make a livelihood Whatever else it may do it should at least train him properly for some occupation Education which thus ministers to self-support is attracting wide attention, and the need for the development of trade schools in all important industrial centers has become everywhere recognized

In this matter of trade schools, Boston merits particular attention as it is especially in advance in this direction The most recent accession to the list of existing educational institutions is the New Wentworth Institute This most important addition to the present educational facilities of the Commonwealth, which are so amply provided and so excellent in many other directions, furnishes new and very much needed opportunities in the industrial field where at present there are none

The new Trade School was founded by the late Arioch Wentworth, a citizen of Boston, who left over three and a half million dollars for the purpose of "Furnishing Education in Mechanical Art."

The aim of the new school is to give young men practical instruction which will enable them to enter industrial life prepared to do and earn from the moment of graduation These courses are for those who wish to become skilled and intelligent artisans and industrial workers, and also for those who wish to prepare themselves for more responsible positions in mechanical and manufacturing plants.

"To furnish education in mechanical arts" is the statement of purpose made by Mr Wentworth in his bequest This phrase defines both the general field of education which the new school occupies, and it also defines with equal definiteness many of its essential characteristics It is a school to furnish education in mechanical arts, in other words, a school to train young men for a higher degree of efficiency in mechanical trades requiring both skill and intelligence than they may attain through any opportunities which are now open to them

The End of the British Naval Airship

THE first naval airship built for the British government by Vickers, Sons & Maxim, at a cost said to be $400,000, was wrecked in Barrow in Furness on September 24th It seems to have been ruined from the same cause that brought about the destruction of so many Zeppelin craft, namely, the impossibility of preventing the airship from being battered against its own shed when half drawn out

The new dirigible, which has been fully described in these columns, never really flew It was taken out on May 23nd, but failed to ascend The builders thereupon undertook to lighten it, and the 23rd ult. finally accepted it on September 23nd.

Electricity

Queen Mary's Fan.—An electric fan has recently been made by the General Electric Company for Queen Mary of England It has been designed to harmonize with the royal toilet articles. It is mounted in gold, and is provided with an ebony switch The fan will be used to dry the Queen's hair, after a shampoo.

Electric Lamps Here and Abroad.—There are in Boston, says the *Electrical Review and Western Electrician*, the equivalent of 1,232 sixteen-candle power electric lamps per thousand of population, in New York 859, in Chicago 730, and in San Francisco 660. European cities show much smaller figures, St. Petersburg having 440, Vienna 246, Paris 185, and London only 4.

Electrocuting the Codling Moth.—The owner of an apple orchard in Spokane has constructed an apparatus with which he hopes to rid his orchard of the codling moth. He uses electric incandescent lamps, surrounded by a metal netting, which is charged with electricity. The moths attracted by the light strike the wire and are instantly killed. The cost of the storage battery and lamps is comparatively small

Electricity from Peat in Canada.—The Canadian government, wishing to arouse interest in the utilization of peat, has built a plant at Ottawa and secured a peat bog of three hundred acres near Alfred, Ontario The plant is equipped to make producer gas from the peat, which will be used in a 60-horse-power four-cycle gas engine, directly connected to a 50-kilowatt dynamo It is estimated that there are 36,000 square miles of peat in Canada, which would yield 28,000,000,000 tons of air-dried peat, which would be equivalent to 14,000,000,000 tons of coal To demonstrate the commercial practicability of utilizing peat for power purposes a building adjoining the Ottawa plant will be fitted up as an ore-dressing laboratory and will be operated by the electricity generated from the peat

Wireless Telegraphy in the Congo.—A recent consular report states that within five years there will probably be 200 wireless telegraph stations in operation in the Congo A Telefunken station is in operation at Boma, the capital of Belgian Congo, and a station of the French Ferrier type at Banana, the principal seaport Each of these is of 1½ kilowatts, but the latter will shortly be increased to 5 kilowatts. The Telefunken engineers expected to erect in September a 5-kilowatt station at St. Paul de Loanda, in the adjoining Portuguese territory at Angola, after which a station was to be established at Leopoldville, on the Congo River. If these stations prove successful, an extensive series of stations will be erected all along the Congo and Kassi rivers The French company expects in the near future to erect a station at Loango, French Congo, and later stations in all the French West African colonies

Electrical Fires in Chicago.—Some interesting facts gathered from the annual report of the city electrician of Chicago are quoted by the *Electrical World* These relate to the electrical inspectors' reports on electrical fires in that city during the year 1910 A table is given to show that there were eighty such fires, with a total loss of $37,550, a small amount compared with the total fire loss Of this amount, one fire caused a loss of $30,000, the cause in this case being the breaking of a lighted portable incandescent lamp, the sparks from which fell into gasoline and oil on the floor The next largest loss was caused by a fire due to sparks from a defective socket falling on chemicals. This defective socket was suspended over the chemicals by lamp cord extended through a metal hood. The loss was estimated by the inspector at $5,000. In all other cases the loss was comparatively slight Of the eighty electrical fires, fifteen were due to low-tension wires short-circuited, nine to motor burn-outs, seven to sparks from motors, five to overheated flatirons, five to wires grounded in conduits, four to low-tension wires grounded, four to defective rheostats, four to lightning, four to short-circuits at fixture outlets, four to breaking of incandescent lamps and the rest to a variety of causes.

Engineering

A Sewer System for Tokyo.—A consular report from Japan states that the city of Tokyo will install a complete system of modern sanitary sewerage before the opening of the world's exposition, which is to commemorate the fiftieth anniversary of the crowning of the Mikado Tokyo has a very large area in proportion to its population, viz., about 100 square miles; hence the installation of sewers will be an immense undertaking The cost is estimated at from $17,000,000 to $20,000,000

The Dreadnought "New York."—Following the "Connecticut" and the "Florida," the keel of the largest of our battleships, the "New York" has been laid at the New York Navy Yard on the same ways on which the two first-named ships were built, and excellent progress is being made upon the ship's floor. A touch of sentiment was lent to the occasion by the fact that the first bolt was put in place by the young grandson of the late Rear Admiral Sampson The "New York" will be 573 feet long, 95 feet, 2 inches broad, will displace 27,000 tons, and will carry ten of the new and very powerful 14-inch rifles

Heat of Exhaust.—Experiments were recently made by one of the leading Swiss firms as to utilizing the waste heat of exhaust gases from internal combustion motors In the present case the Sulzer-Diesel motor was used Water is heated by the exhaust, and the exhaust gases are sent through a set of tubes placed inside a water tank Air for various purposes can be readily heated, for drying ovens or other purposes. One of the main difficulties was to make the tubes of a suitable material so that the exhaust gases would not attack it However it was found that certain special kinds of cast iron will serve the purpose very well.

"Spotting" by Camera.—At present the fall of the shots in target practice is observed from the tops of the cage masts of our battleships and cruisers; the "spotter" noting through his glasses whether the shot falls short or over, or has a deflection to right or left Lieut Com Cleland Davis, whose torpedo has been illustrated in this journal, has invented a method of spotting by the aid of the camera The splash is photographed and in a few seconds the negative is developed The necessary corrections in the range and deflection are then made, and it is stated that the operations are so speedy that there is practically no delay as compared with the present methods of spotting

Lubricating Oil Tests.—From the fact that it is a common practice to use lubricating oil again after filtering it, Messrs Sabatie and Pellet found it of interest to see whether such used and filtered oil showed any great difference from fresh oil Analyses showed this following results The density of the oil is somewhat increased this being no doubt due to the evaporation of volatile portions of the oil The flash point and combustion are a few degrees higher About the same viscosity was observed in both cases The acidity of oils is not changed but the percentage of vegetable or animal oil in mixed oils is considerably lessened. From a practical standpoint the used and filtered oil keeps all its lubricating qualities, provided that care is taken to secure a good filtering so as to remove all the solid particles

Double-decking a City Street.—Chief Engineer Goodrich of the Bureau of Encumbrances, of the Department of Highways, New York, has proposed a plan for the double-decking of 42nd Street, New York, between 5th and Lexington Avenues The street is one of the most congested in the city, there being probably no place in the world where so many systems of transportation center as here The double-decking of the street will give an opportunity for separating the traffic, to say nothing of at once doubling the capacity of the street. Here is a problem which will have to be met and successfully solved as the modern office building twenty to thirty stories in height gradually replaces the older building. Some of the down town streets of New York are already congested almost to a standstill.

Science

An Anthropological Expedition to New Guinea.—*The Geographical Journal* announces that the Committee for Anthropology at Oxford is about to send an expedition for anthropological research to the little known D'Entrecasteaux group, off the eastern end of New Guinea It will be under the leadership of Mr D Jenness, of Balliol, who won distinction at the University of New Zealand before proceeding to Oxford, and who has had practical experience of life in the bush

Ostia.—Director Marino Vaglieri of the National Museum at Rome has opened several Republican tombs in the course of his researches at Ostia, once the chief port of Rome at the mouth of the Tiber A fountain statue of Aphrodite came to light in the Roman theater It is recalled that the Townley Venus in London was found at Ostia The new one resembles another statue of equally Praxitelean style which the late Professor Furtwaengler coupled with the London figure, namely, the Venus of Arles

Horace's Villa.—The exploration of Horace's villa in the valley of the Licenza near Mandela has been resumed by A Pasqui Two sites claim the honor of this name and have divided the pilgrims to the Latin poet's house into camps Both offer scanty remains of Roman country houses Whether Pasqui will find any relics as old as the reign of Augustus is very doubtful But his villa ruin will serve a purpose if it only entices more tourists out of the hot streets of Rome to the outdoor charm of the Sabine Hills

Distribution of the Elements in the Earth's Crust.—The solid crust of the earth with a specific gravity of only about 2.5 as against 5.7 for the entire globe (crust and liquid or semi-liquid interior) is said by Rosenbusch to consist of the various elements in the following proportions by weight Oxygen 47.29 per cent, silicon, 27.21; aluminium, 7.81, iron, 5.46, calcium, 3.77, magnesium, 2.68, sodium, 2.36, potassium, 2.40 hydrogen 0.21, titanium, 0.33, carbon, 0.22, chlorine 0.01, phosphorus 0.10, manganese 0.08, sulphur, 0.02, barium, 0.03, chromium, 0.01

To Remove Tattoo Marks.—Once tattooed, always tattooed, was formerly the rule, but a French army surgeon, Dr Tranchant, has discovered a method of removing tattoo marks, whether made with India ink or lampblack. According to *La Nature*, the process consists of first rubbing the skin until a thin layer of the surface is worn away, then applying a mixture of lime, slaked just before use, and powdered phosphorus The tattooed part having been coated with this paste, a piece of gauze is laid over it, covered with a bandage The dressing is removed after forty-eight hours The scab is allowed to dry in the air, and comes away in about a fortnight, without leaving a scar If any trace of the tattooing then remains, the treatment is repeated Dr Tranchant claims to have applied this treatment in a great many cases, with perfect success

A Cold Winter in the Levant.—According to a report from the American consul at Aleppo, last winter in that vicinity was one of almost unprecedented severity The snow was from two to four feet deep on the level and covered the plains of the entire country around Aleppo, as far south as Bagdad, and north and east to Diarbekir and Mosoul, while the mountainous districts and the railway from Aleppo to Beirut were entirely blocked for a period of about two months, not even the mails arriving for some four weeks If, as we infer from this statement, snow fell in Beirut, it was the first since meteorological observations were begun there upward of thirty-five years ago It is stated that drivers and travelers were frozen to death on the roads, many flocks of sheep perished together with the herders, and numerous families of Bedouins were found frozen in their tents. It is estimated that between 50 and 60 per cent of the sheep were frozen or starved to death, so that there will be a great reduction in the export of skins, wools and stock for meat purposes during the next year or two The olive orchards were also badly damaged.

A Library of the World's Greatest Business Letters

The letters that have sold the *most* goods, collected the *most* money, settled the *hardest* complaints, won the *hardest* jobs, had the *greatest* influence—analyzed and dissected for *you* to learn from, to adapt to your needs, or to develop an original style of your own—with the best examples actually reproduced as they were used and graphically explained point by point.

Here in these three volumes—672 pages—are packed the success-secrets back of the letters that are actually winning the biggest results today, that are bringing orders from you and me, and making other men's fortunes.

Two years of investigation by a staff of experts employed by SYSTEM, the Magazine of Business, were spent collecting the letters of firms and individuals; investigating the actual results; analyzing the comparisons of costs and profits, studying the difference in results obtained by differences in arrangement, wording, enclosures, etc.

Every striking idea found in use by mail order house, wholesaler, manufacturer, retailer, real estate or insurance man, bank, collector, individual salesman or complaint clerk was followed out and its returns studied. This mass of information, this wealth of ideas, this gold mine of absolute fact was then *charted* and *diagrammed*—and developed into one complete, yet concise, library so clear and simple that from it any busy man can pick out for any sort of proposition, an idea or suggestion that he can *know* in advance to be successful; or can turn to for original inspiration.

It is a work that will show any man *how* to write or dictate the kind of letter that arouses attention, tingles with convincing strength, and carries its point, how to conduct a follow-up campaign, how to key results, how to compile and index names, how fit schemes and plans to any proposition.

Special Forced Edition — $1 DOWN

SYSTEM, the Magazine of Business, conducted this exhaustive investigation only for its subscribers. It was not to be given to the general public until 1912. But the subscribers' edition has caused a public knowledge of the tremendous value of the contents, and an extra advance edition has been made imperative. 2640 special sets have been hastily printed.

To make its distribution fair and equitable to all business men, SYSTEM has made the terms as simple as writing your name and as easy as buying your cigars. $1 with the coupon brings to you the complete "Business Correspondence Library"—3 volumes—672 pages, transportation prepaid. $2 per month for 4 months thereafter—less than 7 cents a day—*pays* for them complete and in addition bring you SYSTEM, the Magazine of Business, every month for two full years—24 numbers of this remarkable business magazine, including a copy of

AVIATION

The October Magazine Number of the Scientific American Issue of October 14th, 1911

The next mid-month number of the Scientific American will bear the date, October 14th, 1911. ¶ A large part of the number will be devoted to the more practical aspects of flying. ¶ Besides these articles on aviation, the mid-month number for October will contain the usual Scientific American material, abstracts from current periodicals, the inventor's department, and articles on recent achievements in science and industry. ¶ The whole number will be enclosed in a beautiful colored cover by Mr. Wm. H. Foster.

Please note the change of price of Magazine Numbers—now fifteen cents on all news stands

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING, B.Sc., A.M., C.E.

CRITICISMS

"The first treatise upon aviation which we have seen which may be styled really complete. . . . Actual aeroplane designing is the central theme of the volume. . . . The prominent types are exhaustively compared. . . . The illustrations are a notable feature."
—*Rochester, N. Y., Chronicle.*

"A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplanes. . . . Presents in compact shape the substance of aerodynamic theory. . . . Easily comprehensible to the reader who can concentrate his attention. . . . It is the most scientific popular book on the aeroplane that we have come across so far."
—*New York Sun.*

"Many writers have failed to realize the demand which exists for non-flowery books which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the entire subject. For a writer to steer a straight course between the course of trigonometry on the one hand, and the superficialities of mere discussion on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who has sufficiently divorced himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and information to the less erudite seeker after knowledge."
—*Phila. Inquirer.*

"Students learned in aerodynamics and layman generally interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have realized the future of aerial navigation, and desire a work treating solely of the heavier than air machines written by an acknowledged expert and with no hobbies hidden in the closet."
—*Boston Journal.*

"While enthusiastic in his interest as becomes one who has written so superb a volume, Mr. Loening is also thoroughly versed in the most amazing scientific world discoveries. Here is a work which is at once a history and textbook which may be depended upon for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once new and enlightening with reference to the entire subject and that it is provided in the highest degree with the greatest clearness of style, is but to state the truth."
—*Phila. Press.*

"Mr. Loening has written in such a way that one who wishes to may understand the explanations that are readily given."
—*New York Times.*

12mo. (Outfit linen) 240 Pages, 270 Illustrations. Attractively bound in cloth. Price $2.00 net, postpaid. *An illustrated descriptive circular will be sent free on application.*

WRITING ADDING

Visible and Indivisible

Writing and adding are joined by natural laws. Much writing involves adding; most adding involves writing—both on the same page. Why then a separate writing machine and a separate adding machine?

Our Adding and Subtracting Typewriter is the answer to this question. It has been called two machines in one. It is really one machine with two functions. These two functions are indivisibly joined in practice, and practice demands that they be joined in one machine.

Wherever writing and adding are done on the same page, whether it be in billing work, order work, statement work or any work with similar requirements, the greatest of all labor savers is the

The Old vs. the New

YOU have probably noticed a tendency among bond paper makers to call their product "*Old*," or that some of them appear to take pride in their *old* methods of paper making. Do you know any *other* product whose makers dare *admit* their methods are *old* —much less *claim* it as a *merit*? We don't.

In every industry *improved methods* of manufacture have been the cause of *better quality at the price*. We take pride in the *fact* that the *same* improvement *has* taken place in bond paper making, and that the foremost example of its results is

CONSTRUCTION BOND

The paper that makes "Impressive Stationery at a Usable Price"

And still another *improved* method—one of *sale* and *distribution*—was *introduced* with Construction Bond. You can *not* secure the benefit of it if you use one of these "Old" papers—or, in fact, any other paper than Construction Bond.

While others stand by the *old* method of selling bond paper through paper jobbers, or dealers, a few pounds at a time, we are selling Construction Bond, *direct* to *responsible* printers and lithographers *only* —*500 lbs. or more at a time*. This eliminates the jobber's profit and the expense of handling small lots and assures the user of Construction Bond "Impressive Stationery at a Usable Price"—a price closer to the cost of *production* by *modern methods* than can possibly be secured with any other paper

Waterman's IDEAL Fountain Pen Stands the Test of Microscopic Examination

These are truthful pictures offered for the thoughtful consideration of pen users.

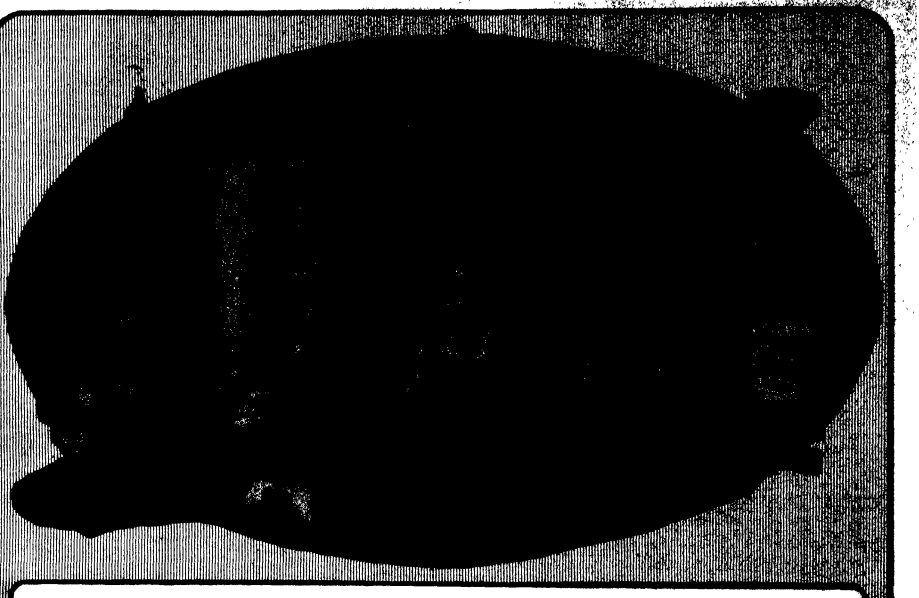
Under a modern, high-power lens, the difference between highly-skilled, hand-made pens and those of the "made-to-sell-cheaply" order is very apparent.

Notice the rough edges, the badly finished writing point, poor "set," all of which cause users to wonder why their pens do not write smoothly and readily.

This reproduces the finish of the pen point used in all Waterman's Ideals.

Under closest scrutiny the utmost nicety of finish and workmanship is revealed. It is the same quality pen point on the $2.50 pen and the pen made for expensive presents.

Notice the absolutely true edges and the perfect grinding of the hard iridium writing point.



The stamp Waterman's Ideal is a guarantee of extreme superiority of finish and quality.

Avoid Substitutes.

Sold Everywhere.

Electricity's Hundred Uses

Using electricity for lighting only is like using a telephone evenings and neglecting its daytime convenience.

Electricity has a hundred uses in addition to lighting—at the turn of a switch this marvelous force produces flameless heat in scores of heating and cooking devices like those shown above.

Electrically heated cereal cookers, frying pans, grids, broilers, hot plates, ovens and ranges are a few more of the many modern electrical conveniences manufactured by this company.

That the General Electric Company has made it possible for **you** to cook by electricity is due primarily to "Calorite", a metal-alloy which transforms electricity into heat as effectively as the metal filament of the Edison Mazda lamp turns electricity into light. "Calorite" is used only in the heating devices manufactured by this company.

Lighting companies and electrical supply dealers everywhere sell these devices. Ask them for illustrated price list of fifty G-E electric cooking and heating devices or write us for it.

THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

VOLUME CV. No. 16.] NEW YORK, OCTOBER 14, 1911 [15 CENTS $3.00 A YEAR

View from below dam, showing huge sections of the wall pushed bodily down stream.

The Failure of the Austin Dam

A Call for State Legislative Control

THE complete failure of the Austin dam, with its resultant loss of property and human life, has naturally drawn attention to the early history of this structure. The dam was constructed in the year 1909, to replace a smaller dam higher up stream built about eleven years previously, for the purpose of impounding the water required for a pulp mill. The width of the valley at the point where the new dam was placed is 250 feet, and the reservoir was designed to impound 200,000,000 gallons of water, with the spillway 42 feet above the level of the valley. The width of the dam at the top was 2 feet 5 inches, at the bottom 36 feet. The length of its upper face was 544 feet. The rock foundation of the valley consists of horizontal layers of sandstone with shale sandwiched in between. The building of the dam, which contained about 16,000 cubic yards of concrete, was begun in May and completed about December 1st, 1909. In preparing the foundations, about 6,000 cubic yards were excavated, and an earth embankment was laid against the upstream face of the dam at a slope of 3 : 1, reaching within 27 feet of the normal water level.

The concrete structure was reinforced with twisted steel rods 1¼ inches in diameter and 25 feet long, placed 2.7 feet apart. On either side of the spillway a bulkhead was built, which also was reinforced with millinch steel rods, as was the top of the dam. Very significant is the fact that, upon completion of the dam, there was found to be a crack extending from the top to the ground level, and in December, 1909, a second crack appeared, about January 17th, 1910, the weather was warm, and abundant rain fell. On the 21st of January, the dam was overflowing. On Monday, the 23rd, water was found to be leaking from the toe of the dam. It was suggested at the time that the failure of the dam to withstand the flood of 1910 was due to two causes. First, the great bulk of the hurriedly built concrete, some of which was laid in freezing weather, and completed only six weeks before the time when the maximum pressure occurred, secondly, the seepage of water through the rock strata under the dam.

As far as we can learn, the work done upon the dam at this time in the way of investigation of conditions and of provision against further damage, was altogether inadequate, particularly in view of the fact that heavy seepage had taken place through the porous material below the foundation. The least that could have been done would have been to sink a curtain wall through the underlying rock, etc., carrying it down everywhere to a thoroughly impervious stratum. Failing this, the dam should have been abandoned altogether.

In the construction of storage dams, of whatever character, it is an axiom that there should be no suspicion whatever as to the impermeability, not merely of the dam itself, but of the natural formation upon which it is laid. There is no mystery about the construction of watertight dams. The problems connected with their foundations and with the stresses in the dams themselves are perfectly well understood among competent engineers, and have been so understood for a long period of time. We know of no engineering work regarding which the possibilities of failure are so many, and their results so serious, as that which has to deal with the impounding of vast quantities of water by the erection of artificial barriers. Thanks to accumulated stores of knowledge, and to the very thorough training, theoretical and practical, to which the competent civil engineer is subjected, both at the engineering schools and colleges and in his subsequent career, there is abundance of high class professional skill available for those individuals or corporations who wish to undertake the construction of works of this character.

One of the most important lessons of this disaster is that which teaches the necessity for the employment of engineers skilled in this particular branch of work. Another lesson is that when the engineer has been engaged, he should be left an absolutely free hand in determining the character of the construction that should be employed. To engage an engineer to design a dam of importance and then impose a limit of cost is to tempt him to play fast and loose with the ethics of his profession, and imperil the safety of the proposed structure.

The photographs of the wrecked dam and the devastation which was caused by the flood of water that swept through the valley below tell their own story so clearly that but little comment is necessary. If we bear in mind that seepage was occurring below the foundation, the probable sequence of events, as the dam gave way, is easy to understand. We spoke early in the present article of certain cracks that appeared when the dam was first filled with water. Very significant is the fact that one of the largest breaks in the dam wall occurred along the very lines of these old fractures. Settlement due to gradual washing out of the underlying porous material, coupled with changes of temperature, may have induced the original cracks. Further washing out below the foundations would cause these cracks to become complete lines of cleavage. Then it was that the loss of transverse

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Mind and Mechanism

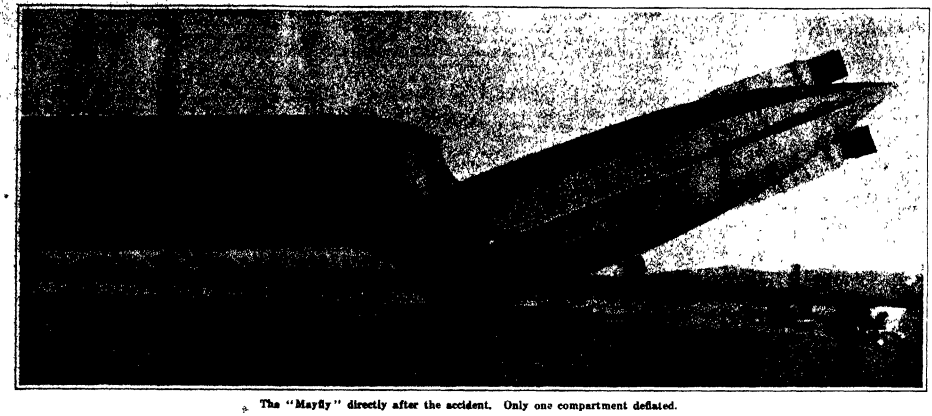
It has been pointed out that the mechanical aids which man has devised to assist him in his varied pursuits of daily life are subject to an evolution precisely similar in character to that which governs the development of living organisms. In this evolution of our mechanical adjuncts there is a tendency to transfer to them a greater and greater share of the functions originally performed by man himself. Thus the rude implements of primitive man, the cudgel, the stone hammer, may be regarded as a modified arm, a fist remodeled to adapt it to a special end. The energy for the action of such simple tools is supplied directly by the operator, without undergoing any fundamental modification on its way to the point of application. Later came levers, engines of war, and various instruments of more complicated character. Here the energy is in most cases still derived from the primitive source, the human body, but its factors undergo various changes, as in the lever, which, by lengthening the path of travel of the point of application, secures a proportionate gain in the mechanical power available—or in the crossbow, which stores up in the form of elastic strain the work done by the muscles of the arm. This pent up energy, when suddenly released by the action of the trigger, speeds the deadly missile at the foe. The bowman, having in a separate act charged his weapon with the strength of his arm, is, in the second stage of the process, free to give his whole attention to the aim.

But man early found means to supplement the limited powers of his body from more lavish sources —the wind, the running stream, were pressed into his service. Then came explosives, and last of all the patient steam engine. And now becomes apparent a new feature. The new servant does more than merely replace the hand, the arm, or the feet that carry us from place to place. The inventor has, as it were, breathed into his creature a part of his own sentient soul. In orderly sequence, and with a precision that defies imitation by human hands, a legion of tireless engines in the factories throughout our land perform innumerable tasks that seem to require the guidance of a reasoning mind. The co-ordination centers of the inventor's brain have, as it were, been implanted in the machine. Nor is this all. Such purely mental a task as numerical computation is now intrusted, with great saving of time and brain-fatigue, to the mechanical calculator. Indeed, a machine has been built, which, when given the premises of a problem, will, by purely mechanical manipulation, complete the argument and set forth the logical conclusion. This "logical machine," it is true, is at the present time but a scientific curiosity and perhaps will always remain so.

Coming right down to current events, a most instructive and interesting case is presented to us in the Doutre aeroplane stabilizer recently described in our columns. The action of this apparatus displays all the characteristic features of the "sensory motor circuit" of psychology. Throughout all the interactions of the individual with the external world there runs a cycle. The first link in the chain is, as a rule, a stimulus from outside, causing a "sense impression" in some one or other of our organs of special sense, such as the eye, the ear, or the tactile papillæ of the skin. Occasionally an "internal sense" such as our sense of orientation or equilibration may take the place of our consciousness of things without. In the last stage the cycle returns again to the external world, the action being now reversed, the organism reacting upon its environments. Intermediate between these two stages there is necessarily a connecting process, which may be intensely complicated, involving all the intricacy of a long chain of mental operations; in other cases the connection is at least seemingly simple. The sensory motor circuit appears most clearly in so-called reflex actions, for here the successive steps occur in immediate sequence. Thus a sudden loud report produces an instant quiver of the eye-lid; if through some accident the balance of our body is upset, reflex action, through the medium of our sense of equilibrium, located in the semi-circular canals of the inner ear, immediately calls out a righting motion in the requisite muscles. Consciousness does not necessarily enter into these effects, which, indeed, continue during the lighter stages of anæsthesia, but, as has already been indicated, conscious action is subject to the same cycle. This is obvious enough when the reaction follows close upon the stimulus, as, for instance, when the sight of some desirable object induces us to put forth our hand and seize it. But in the great majority of cases, in the infinite variety of our daily activities, the reaction is "delayed" and many complicated steps of mental and emotional experience intervene between the data furnished by our senses and the action based upon them. But however complex these data may be, involving often the entire previous history of the individual; however intricate the maze through which the mind weaves its thread from the entrance to the soul, a sense perception, to-the final goal, the reaction upon the environment: the same sensory motor circuit is discernible throughout. For all the contents of our mind are ultimately referable to sense impressions.

The Doutre stabilizer is equipped with an anemometer plate which responds to variations in pressure, thus, as it were, informing the apparatus of external conditions, just as our eye, our ear, our sense of touch, keep us informed of the state of the world around us. More than this, by a suitable mechanical connection, the stimulus thus applied to the anemometer, by relay action, sets free a store of energy which actuates an auxiliary motor. This reacts upon the environment in such a way as to preserve the aeroplane from accident. Furthermore, the Doutre stabilizer comprises an element which is the exact counterpart of some of our internal senses. The apparatus reacts not only to changes in external conditions, but also to changes of its own speed. A number of gliding weights are partially free to move relatively to the body of the aeroplane. According to the laws of dynamics, they will do so, owing to their inertia, as soon as the aeroplane suffers an acceleration. The relative motion of the gliding weights with reference to the body of the aeroplane is made to actuate the auxiliary motor, and again we have an exact counterpart of reflex action, designed to maintain the "life" of the machine.

Had the inventor set to work with the deliberate intention of preparing a mechanical model illustrating reflex action, he could hardly have produced a more perfect example than is presented to us in the Doutre stabilizer.



New York's Budget Exhibit

THE necessity for technical men and scientific methods in the administration of the modern city is one of the most impressive lessons to be derived from the Budget Exhibit now being held in the city of New York for the information and instruction of its taxpayers. Taking place in October at a time when the annual discussion of the city's appropriations for the ensuing year is in progress, this exhibition supplies a full and illustrated record of the activities of the municipality. Like any large private corporation, a city requires efficiency of management and systematic cost accounting just as if it were concerned with manufacturing or transportation; but on account of political conditions, charter and other legislation, and, even more largely, lack of interest and dense ignorance on the part of the citizen stockholders, municipal efficiency and economy are more difficult of realisation. However, they are the keynotes of all practical municipal administration no less than of the successful conduct of industrial operations, and to the interested taxpayer in such a city as New York they figure prominently at the time of the adoption of the annual budget by the Board of Estimate. To this body must come the heads of all the city departments, with their requests for appropriations for the ensuing year, properly analyzed and classified, and with a record of work accomplished under previous appropriations. To secure the appropriations asked for, the department heads must convince the Board of Estimate and the taxpayers of the city that their estimates are reasonable and the record of their work such as to warrant the desired appropriation, or as much thereof as the best interests of the city will permit.

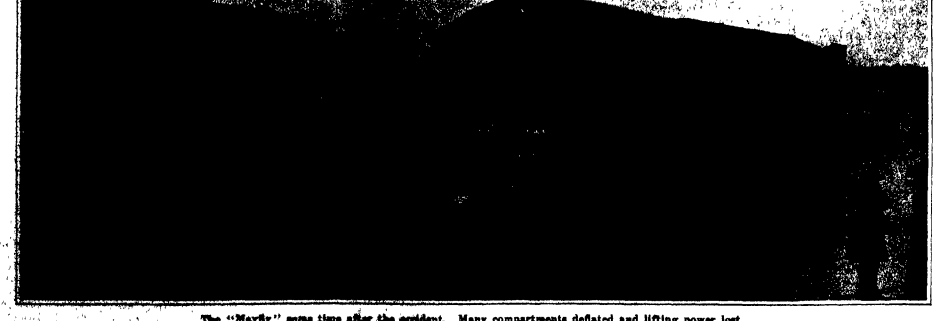
To get the greatest publicity for these different departmental statements, which in 1910 included the eighteen hundred items that went to make up a $174,000,000 budget, the city of New York for two years past has hired an unoccupied mercantile building on Broadway, where are displayed such charts, diagrams, photographs, and appropriate objects as best illustrate the needs and work of each department, bureau or office. In many cases, such as departments of law and finance, the exhibit is merely statistical or a summary; but in others there are displayed photographs, specimens, apparatus, or machinery which show the application of modern science and engineering to municipal problems and conditions, and the resulting increase in efficiency and economy by the adoption of recent inventions and improved scientific methods. For example, child hygiene, and food and milk inspection are items calling this year for largely increased estimates by the Health Department. At the Budget Exhibit can be seen charts showing what has already been accomplished along these lines together with statements of what is desired. To give point to this there are shown actual photographs contrasting wholesome conditions with those which give rise to disease; also the various physicians, nurses, inspectors and other officials of the department are portrayed at work in schools, tenements, milk stations, and even at the farms. To support the demand of the Fire Commissioner for appropriations for new motor apparatus, there may be seen at the exhibition a high-power gasoline pumping engine, that has recently passed the rigorous requirements of the department engineers, and a modern motor hose wagon temporarily withdrawn from active service. Interesting as these are as engineering novelties, it is in connection with their surprising economy that they find place in the budget exhibit, eliminating as they do the more expensive fire horse, an honored specimen of which is stabled hardby the new apparatus. The best methods of fire-proof construction and fire prevention, soon to be enforced by a new Bureau of Fire Prevention, are also shown.

The Department of Docks and Ferries by plans, photographs and models shows its comprehensive schemes for developing and increasing the water front to provide much needed facilities for commerce. The Department of Water Supply, Gas and Electricity shows the various devices used in the distribution and measurement of water, with some interesting relief maps by which the history of water supply and distribution is shown from the time of the settlement of the city. The progress of the great Catskill Aqueduct is also graphically illustrated by photographs and models, and a comparison is made with previous supply systems.

These few instances are but typical of the many exhibits, both graphic and practical, that make up this most interesting display; but they like others serve to emphasize that close connection between municipal economy and scientific work which is not always realised outside the ranks of municipal engineering. If the lives of the poor and particularly of infants are properly to be safeguarded the testing of milk and food must be done in the laboratory and standards adopted for the inspectors. Improved fire apparatus must be supplied, if adequate protection is to be furnished to buildings that are ever increasing in number, volume and height. New docks for the commerce of the future and to produce revenue for the city must show the best civil engineering of the day. These projects, illustrated and described, do, or should, represent the best engineering of the time. And the citizen who examines the vast budget of the city for its current expenses as well as the bonds issued for permanent improvement, must have the conclusion forced upon him that it is the engineer rather than the politician who should be primarily responsible for conducting the affairs of a great city, at least if efficiency and economy are to be secured. Even under present conditions the part played by the former is greater than many would suspect. It is the engineer, the architect, the sanitarian, the physician, the landscape gardener and other workers of applied science that make our cities. Their influence equals, if it does not surpass that of our legislators and politicians. This fact is impressed strongly upon every understanding visitor to the Budget exhibition.

The "Mayfly" directly after the accident. Only one compartment deflated.

Wreck of the British Naval Airship "Mayfly"



Penalty of Launching a Rigid Dirigible in a Cross Wind

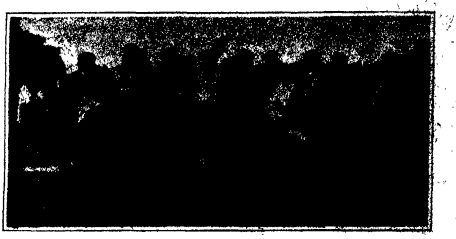
By Carl Dienstbach

RATHER a striking contrast is offered by the pitiful wrecking of the first non-German rigid dirigible, the British naval airship "Mayfly," which broke in two before it even got into the air, and the many excellent performances of Count Zeppelin's new "Schwaben," which at last completely fulfills what the advocates of the rigid system and of the mammoth dirigible so long promised seemingly in vain. When the British ship first came out, it claimed a considerable advance over the Zeppelins, but before its trials could begin in earnest, even its claimed superiority had been far surpassed by the "Schwaben's" actual performances. Its ultimate fate seems to offer a striking object lesson of the fallacy of judging the merits and demerits of a theory from isolated experiences.

It is interesting to try analyzing the causes of this accident from the point of view of the Zeppelin practice. It must be pointed out as a fundamental mistake for an airship to be taken on water from a stationary shed on land in side wind, even though a light one. In 1906 Zeppelin and his engineers had much yet to learn, but even then they were careful to avoid taking the "Zeppelin II." from its stationary shed on the shore of Lake Constance, near Manzell, when the slightest wind was blowing across the entrance. The number of trials that season was much limited on that account, but no exception was made to the rule. It is difficult to hold an airship against lateral wind pressures, and the cars floating on the water and partly submerged cannot yield to a gust as quickly as over land. For this reason the principal Zeppelin sheds on the lake were floating structures, which always swing automatically into the direction of the wind.

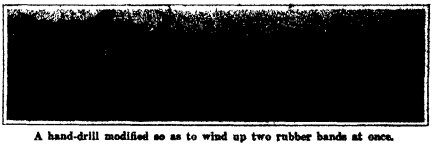
Much light is further shed on the naval dirigible's misfortune if we recall that the first frame attempted by its builders was avowedly a complete failure, and that right before the first "coming out" of the ship there had been trouble from the tearing and leaking of the internal gas bags. The first picture of the accident shows the damage all confined to one compartment, and it is reported that the accident originated with the tearing of the gas bag contained in this compartment. The simplest consideration shows how very much the structure of a rigid dirigible is weakened if one compartment near its center should suddenly be deflated. It is a fundamental fact that the solidity of a rigid dirigible results chiefly from aerostatic pressure of the gas in its different compartments. The frame of the first "Zeppelins" partly collapsed over night, when there was no gas in the ship, and some of the ropes by which it was suspended from the ceiling of its shed gave way for some unexplained reason. But if the whole hull represents two halves with gas in each, the case is worse. All the leverage of the lift in these halves is then exerted against the framing of that single compartment, the weight of each car acting as a fulcrum. If there were gas in it, this compartment would not only compensate the strain to a certain extent by its own lift, but furthermore, the pressure of the gas sideways, against the flat ends of the cylinder formed by its gas bag, would most strongly brace it against exactly the kind of strain it encounters. At the point where the strain tries hardest to crush the longitudinal members by compression, namely, along the top, the side pressure of the gas is strongest. One needs but to recall the appearance of an ordinary spherical balloon immediately after inflation. Every rope has then been "frozen" into a rigid bar, and the ordinary rules of architecture are in a way exactly reversed, for everything is pushing up and trying to "flare" toward the top. In a rigid airship the compression strength of the many single members of the frame becomes all powerful if it is aided by this force. Without the gas lift, a member of a rigid frame is strictly "rigid" only for a certain limited distance, as is so well shown in the sad collapse of the naval dirigible's body shown in the second picture, after deflation. Indeed, the frame of a rigid airship should by no means be so weak in itself as to break if a single central compartment should become deflated. The incident on the "Zeppelin III's" trip to Berlin 1909, when the flying blades of a burst propeller pierced the hull, without causing an accident, shows how much resistance it may offer.

The "Mayfly" some time after the accident. Many compartments deflated and lifting power lost.



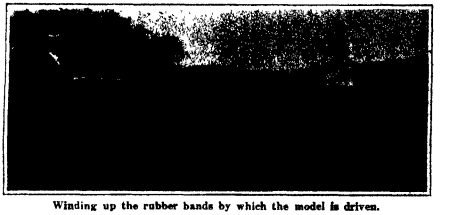
How to Make a Model Aeroplane

A Monoplane Driven by Elastic Rubber Bands Which Will Fly 700 Feet



By Cecil Peoli

AFTER the problems of flight had been so far solved that men could take the air with reasonable safety, it was but natural that boys, who like everything that "goes," should take an interest in the flying machine. It is not too much to say that most boys from twelve to eighteen know more about the actual construction of aeroplanes and the difficulties of building and operating them than their grown-up relatives, who stand open-mouthed in the contemplation of spiral dips, figure-of-eight curves, and other antics.



The interest of boys in aeroplanes has led them to build small models of their own. With these, remarkable results are obtained, so remarkable indeed that in the hands of a skillful scientific experimenter, they might be used for the purpose of clearing up some of those mysteries of dynamic flight which are still concealed. Although the results obtained with small models are not always directly transferable to the full-sized machine, there can be no doubt that they will serve the useful purpose of performing at a small expense, in a rough yet sufficiently accurate way, the work which is now being done by costly aerodynamic institutions.

A group of boys at Van Cortlandt Park, all of whom have made their own model aeroplanes.

A hand-drill modified so as to wind up two rubber bands at once.

Winding up the rubber bands by which the model is driven.

Feats Accomplished With Small Models.

The rivalry among boys in the building of safe, stable models is so keen that model-flying contests are held from time to time in various parts of the country, notably at Van Cortlandt Park, New York city. The amount of interest that is aroused is impressive to the man who is unfamiliar with the spread of the model making movement among boys. The feats accomplished by the models are indeed remarkable. One of them, devised by the writer of this article, has flown for a distance of 1,691 feet, driven only by rubber bands. The model which is here illustrated, is built along somewhat similar lines, and will fly for about 700 feet. A boy of an experimental turn of mind can supply it with supporting surfaces of different size and shape, and probably increase its flying range considerably. At all events, the possibilities for experimenting, if the boy who makes this aeroplane is of an inquiring turn, are almost unlimited.

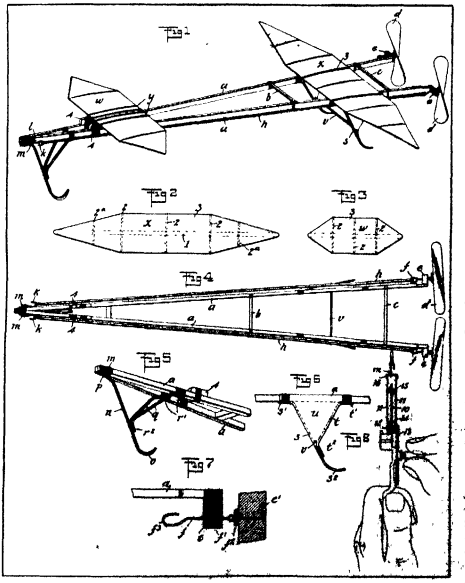
Aeroplane models are sold in stores throughout the country. They undoubtedly fly—some better than others. Their cost ranges from two to five dollars, and upward. The model here shown can be made for much less and will outfly almost any bought model.

The Main Frame.

The main frame of the model monoplane consists of two strips *a* of spruce, each 28 inches long and measuring in cross section ¼ by ⅜ of an inch. As shown in Fig. 1, the two strips *a* are tied together at the front and with strong thread and are then glued, the glue being spread over and between the windings of the thread. (Figs. 1 and 5.) The rear ends of the two strips *a* are spread apart 4½ inches to form a stout triangular frame, and are tied together by cross bars of bamboo *b* and *c*, which are secured to the main strips *a* by strong thread and glue.

The Propellers.

The propellers *d* are two in number and are carried by the two long strips *a*. Each propeller is five inches in diameter, and is whittled out of a single block of white pine. The propellers have a pitch of about ten inches. After the whittling is done they are sand-papered and coated with varnish. The thickness of the wood at the hub (*e'*, Fig. 7) of the propeller should be about ⅜ of an inch. At the rear ends of the strips *a* bearing blocks *e* are secured. These bearing blocks are simply small pieces of wood projecting about ⅝ of an inch laterally from the strips *a*. They are drilled to receive a small metal tube *f'* (steel, brass, or copper), through which tube the propeller shaft *f* passes.



The propeller shaft itself consists of a piece of steel wire passing through the propeller hub and bent over the wood, so that it cannot turn independently of the propeller. Any other expedient for causing the propeller to turn with the shaft may obviously be employed. Small metal washers *f'*, at least three in number, are slipped over the propeller shaft so as to lie between the propeller and the bearing block.

That portion of the propeller shaft which projects forwardly through the bearing block *e* is bent to form a hook *f''*. To the hook *f* rubber strips *h*, by which the propellers are driven, are secured. The rubber strips are nearly as long as the main strips *a*. At their forward ends they are secured to a fastening consisting of a double hook *k l*. The hook *k* lies in a horizontal plane, the hook *l* in a vertical plane. The hook *k* holds the rubber strips, as shown in Figs. 1 and 4, while the hook *l* engages a hook *w*. This hook *w* is easily made by passing a strip of steel wire through the meeting ends of the main strips *a*, the portions projecting from each side of the strips being bent into the hooks *w*.

The Skids.

Three skids are provided, on which the model slides, one at the forward end, and two near the rear end. All are made of bamboo. As shown in Fig. 5, the front skid may be of any length that seems desirable. A 6-inch piece of bamboo will probably answer most requirements. This piece *n* is bent in opposite directions at the ends to form arms *o* and *p*. The arm *o* is secured to the forward ends of the two strips *a* constituting the main frame, by means of thread and glue. The strips and skid are not held together by the same thread, but the skid is attached to the two strips after they have been wound. Hence there are two sets of windings of thread, one for the two strips *a* themselves, and another for the skid and the strips. Strong thread and glue should be used, as before. In order to stiffen the skid, two bamboo struts *q* will be found necessary. These are bent over at the ends to form arms *r'* and *r''* (Fig. 5). Each of the arms *r* is secured to the under side of a strip *a* by strong thread and glue. The arms *r'* are superimposed and tied to the bamboo skid *n* with strong thread and glue.

The two rear skids, of which one is shown in Fig. 6, consist each of two 5-inch strips of bamboo *s*, likewise bent at either end in opposite directions to form arms *s'* and *s''*. The arms *s'* are fastened to the strips *a* by strong thread and glue. To stiffen the skids a strut *t* is provided for each skid. Each strut *t* consists of a 3-inch strip of bamboo bent over so as to form arms *t'* and *t''*. The arm *t'* fits the under side of the main strip *a*, the arm *t''* the skid *s*. Strong thread and glue are employed to fasten each strut in position on the strip *a* and the skid *s*. In the crotch of the triangular space *u*, formed by the skid *s* and the strut *t*, a tie bar *v* (Figs. 4 and 6) is secured by means of thread and glue. This tie bar *v* connects the two skids, as shown in Figs. 1 and 4, and serves to stiffen them. The triangular space *u* is covered with paper, preferably bamboo

Details of the model aeroplane.

paper. If bamboo paper is not available, parchment or very light paper of some kind may be used. It does not need to be waterproof. Thus triangular fins are formed which act as stabilizing surfaces.

The Main Planes.

The main planes are two in number, but are different in size. Contrary to the practice followed in large man-carrying monoplanes, the front supporting surface is comparatively small in area and the rear supporting surface comparatively large. Those supporting surfaces *w* and *x* are shown in detail in Figs. 2 and 3. It has been found that a surface of considerable area is required at the rear of the machine to support it. Hence the discrepancy in size. Although the two supporting surfaces differ in size, they are made in exactly the same manner. Each consists of a thin longitudinal piece of spruce 1, to which cross pieces of bamboo 2 are attached. In the smaller plane (Fig. 3) all the cross pieces 2 are of the same size. In the larger plane (Fig. 2) the outer strips 2a are somewhat shorter than the others. Their length is 3½ inches, whereas the length of the strips 2 is 8¼ inches. In order to allow for the more gradual tapering of the plane, around the outer ends of the longitudinal strips 1 and the ribs 2, a strip of bamboo 3 is tied. The frame, composed of the longitudinal strip 1 and cross strips 2 and 2a, is then covered with bamboo paper, parchment paper, or any other stiff light paper, which is glued in place.

The forward or smaller plane has a spread of 8½ inches and a depth of 3¼ inches. The main plane has a spread of 20 inches and a depth of 3½ inches at the widest portion. The author has made experiments which lead him to believe that the tapering form given to the outer edge of the plane improves both the stability and endurance of the machine.

The planes are slightly arched, although it will be found that flat planes will also give good results. The rear edge of the main plane should be placed 4¼ inches distant from the forward edge of the propeller block *c*.

The front plane must have a slight angle of incidence, just how much depends upon the weight of the machine, the manner in which it is made, and various other factors. This angle of incidence is obtained by resting the front portion of the plane on two small blocks 4 (Figs. 1 and 5) which are fastened to the top of the main strip *a* by strong thread and glue.

The height of the blocks 4 should be about ¼ of an inch, although this will necessarily vary with the machine. The blocks should be placed approximately four inches from the forward end of the machine. The front end of the forward plane should be elevated about one-fourth of an inch above the rear end, which rests directly on the main strips *a*.

Both the front and rear planes *w* and *x* are removably lashed to the frame by means of ordinary rubber bands, which may be obtained at any stationery store. These rubber bands are lettered *y* and *z* in Fig 1

Winding the Rubber Strips.

The rubber strips can be most conveniently wound up by means of an egg beater, slightly changed for the purpose. The beater and the frame in which it is carried are entirely removed, leaving only the main rod 10, which is cut off at the lower end so that the total length is not more than two or three inches The two brass strips 11 on either side of the rod, which are attached to the pinion 12, meshing with the large driving wheel 13, are likewise retained A washer 14 is soldered to the rod near its upper end, so as to limit the motion of the small pinion 12 and the brass strips 11 attached to the pinion Next a wire 15 is bent in the form of a loop, through which loop the central rod passes The ends of the wire are soldered to the side strips 11 Lastly, a piece of wire 16 is bent and soldered to the lower ends of the side strips In order to wind up a rubber strip, the strip is detached from the forward end of the model, and the hook *m* slipped over the wire 16 The opposite end of the rubber band is held in any convenient manner Naturally the two strips must be wound in opposite directions, so that the two propellers will turn in opposite directions By stretching the rubber while it is being wound, more revolutions can be obtained It is not safe to have the propeller revolve more than 700 times The ratio of the gears of the egg-beater winder can be figured out so that the requisite number of twists can be given to the rubber bands for that particular number of revolutions

Instead of an egg beater, a hand drill can be used as shown in one of our photographs This, however will have to be also modified for the purpose, a wire hook being inserted in the jaws In the modified drill here presented, an extra gear has been provided so that the two rubber bands may be wound up at the same time in opposite directions

Rules Governing the Competition for the $15,000 Flying Machine Prize Offered by Mr. Edwin Gould

1. A prize of $15,000 has been offered by Mr. Edwin Gould for the most perfect and practicable heavier-than-air flying machine, designed and demonstrated in this country, and equipped with two or more complete power plants (separate motors and propellers), so connected that any power plant may be operated independently, or that they may be used together.

CONDITIONS OF ENTRY

2. Competitors for the prize must file with the Contest Committee complete drawings and specifications of their machines, in which the arrangement of the engines and propellers is clearly shown, with the mechanism for throwing into or out of gear one or all of the engines and propellers. Such entry should be addressed to the Contest Committee of the GOULD-SCIENTIFIC AMERICAN Prize, 361 Broadway, New York city. Each contestant, in formally entering his machine, must specify its type (monoplane, biplane, helicopter, etc.), give its principal dimensions, the number and sizes of its motors and propellers, its horse-power, fuel-carrying capacity, and the nature of its steering and controlling devices.

3. Entries must be received at the office of the SCIENTIFIC AMERICAN on or before June 1st, 1912. Contests will take place July 4th, 1912, and following days. At least two machines must be entered in the contest or the prize will not be awarded

CONTEST COMMITTEE.

4. The committee will consist of a representative of the SCIENTIFIC AMERICAN, a representative of the Aero Club of America, and the representative of some technical institute. This committee shall pass upon the practicability and efficiency of all the machines entered in competition, and they shall also act as judges in determining which machine has made the best flights and complied with the tests upon which the winning of the prize is conditional The decision of this committee shall be final.

CONDITIONS OF THE TEST

5. Before making a flight each contestant or his agent must prove to the satisfaction of the Contest Committee that he is able to drive each engine and propeller independently of the other or others, and that he is able to couple up all engines and propellers and drive them in unison No machine will be allowed to compete unless it can fulfill these requirements to the satisfaction of the Contest Committee. The prize shall not be awarded unless the competitor can demonstrate that he is able to drive his machine in a continuous flight, over a designated course; and for a period of at least one hour he must run with one of his power plants disconnected; also he must drive his engines during said flight alternately and together. Recording tachometers attached to the motors can probably be used to prove such performance

In the judging of the performances of the various machines, the questions of stability, ease of control and safety will also be taken into consideration by the judges The machine best fulfilling these conditions shall be awarded the prize

6 All heavier-than-air machines of any type whatever—aeroplanes, helicopters, ornithopters, etc.—shall be entitled to compete for the prize, but all machines carrying a balloon or gas-containing envelope for purposes of support are excluded from the competition

7 The flights will be made under reasonable conditions of weather The judges will at their discretion, order the flights to begin at any time they may see fit, provided they consider the weather conditions sufficiently favorable

8. No entry fee will be charged but the contestant must pay for the transportation of his machine to and from the field of trial

9 The place of holding the trial shall be determined by the Contest Committee, and the location of such place of trial shall be announced on or about June 1st, 1912

10 Mr Edwin Gould, Munn & Co. Inc publishers of the SCIENTIFIC AMERICAN, and the judges who will be selected to pass upon machines are not to be held responsible for any accident which may occur in storing or demonstrating the machines on the testing ground

A Weather Forecasting Competition

THE Société Française de Navigation Aérienne has decided to organize a competition in weather forecasting, which will extend over a period of two weeks about the time of the vernal equinox of next year. This season was selected because it is supposed to be characterised by generally unsettled weather, and therefore likly to afford a severe test to the competitors. An elimination contest, the particulars of which have not yet been announced, will precede the principal competition, its object being to shut out the cranks and charlatans who might be disposed to participate in such an event.

The idea of a public contest in weather forecasting is not new. In the autumn of 1905 a competition of this sort was held by the Société Belge d'Astronomie for a prize of 5,000 francs. The competitors were first required to make daily forecasts based on the current weather maps published at the various meteorological centers of Europe; these were submitted by telegraph and registered mail to the jury assembled in Belgium, the members of which were all well-known meteorologists, viz., Messrs. Teisserenc de Bort, Hatch, Pelle, Brunhes, and Vincent. From the twenty-four contestants the seven who submitted the most accurate forecasts were summoned to Liége to take part in a further test. Each of them was required to make a series of forecasts for a twenty-four hour period based upon seven weather maps selected at random from those published by the French meteorological service between the years 1880 and 1902 The jury, having at hand the maps for the days succeeding those selected, was able immediately to verify the accuracy of the predictions

This second test resulted in the further elimination of four competitors, and the remaining three were then required to furnish a statement of their methods of forecasting. The jury unanimously awarded the prize to M. Gabriel Guilbert, of Caen, France, both for his successful forecasts and for his method, which was then first made known to the scientific world, and attracted wide attention.

M. Guilbert has since published a book on weather forecasting.[1]

The Mine-safety Demonstration

A NATIONAL mine-safety demonstration will be held at Pittsburg, Pa., on October 30th and 31st, 1911, under the auspices of the Bureau of Mines. The first day will be devoted to demonstrations at the Bureau of Mines' building in the Arsenal grounds, Fortieth and Butler streets, including exhibits of explosives, safety lamps, fuel testing, etc., and actual explosions. On the same day demonstrations and explosions will be given in the experimental mine near Bruceton, ten miles south of Pittsburg On the second day the demonstrations will be held at Forbes Field the National League baseball grounds This programme will include a first aid exhibit, rescue work and mine gas President Taft will be present and award the prizes, and will afterward be entertained at luncheon at the Hotel Schenley It is expected that the Bureau of Mines will run a special car from Washington to accommodate the officials of the Federal government There is at present prevailing a deep interest in the subject of mine safety appliances and many heads of bureaus and departments will grasp this opportunity of having ocular demonstration of the excellent work being accomplished by the Bureau of Mines Dr Holmes, the Chief of the Bureau, will, of course, be in charge of the demonstrations

A Stabilizer for Aeroplanes

A FLYING machine having stabilizing means arranged longitudinally and both in front and rear of the vertical turning center of the machine is shown in a patent, No. 1,001,120, to Joseph A Blondin of Los Angeles, Cal. The stabilizing means include a plurality of members which may be moved laterally to varying degrees which are connected to a movable aviator's seat, thus permitting the convenient operation of the stabilizing members

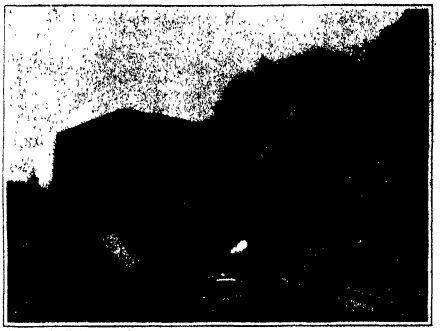
(Continued from page 331.)

strength plus the reduction of resistance to sliding of the dam upon its undermined base, brought the strength of the dam below the yielding point, and the water burst through. Some broken sections of the wall appear to have been turned completely about their base, others have been pushed bodily downstream upon their base, remaining erect.

There have been altogether too many failures of dams in this country during the past two decades. There is need for State legislative control. Individuals and private corporations should not be left at liberty to build where and how they will. The menace of a badly-designed and ill built dam is so great, that the plans for all structures of this character should be referred to an expert board, appointed by the State, and strongly backed up in all its decisions.

Hail Insurance

THE insurance of growing crops against hail though little practised in the United States, is an old and well-established institution in many parts of Europe. The first hail insurance company was organized in Scotland in the eighteenth century. A large mutual hail insurance company was founded at Brunswick, Germany, in 1791, and another at Neubrandenburg, Germany, in 1797. To-day there are scores of companies in Europe. The greater number of these are conducted on the mutual plan, though there are also many stock companies. In several countries hail insurance companies enjoy a government subsidy, while in one, Bavaria, the government itself insures agriculturists against hail. A similar plan is in operation in the Canadian territory of Alberta, where hail insurance is conducted by the Treasury Department.



From time immemorial mankind has endeavored to find some physical means of preventing hailstorms. In antiquity the custom of hurling javelins and other missiles against clouds that threatened a discharge of hail was widespread. In the middle ages the aid of the "tempestarii" sorcerer who claimed the power of influencing the weather—was invoked to the same end. Bells, also, were believed to be efficacious in averting hailstorms. Early in the nineteenth century metal tipped poles, called *paragrandines* or *paragreles*, imitated from lightning-rods, were set up in great numbers in many parts of Europe, in the belief that they would draw off the free electricity of the air, which was assumed to be the chief cause of hail storms. About 1896 the custom of "hail-shooting" was introduced in Europe, especially in vine-growing districts, and soon became immensely popular. This consisted in bombarding the clouds with various special forms of cannon. In the year 1900 five hundred of these cannon were in use in France and Spain, 2,000 in Austria-Hungary, and 10,000 in Italy. This custom still flourishes. In Austria and Italy it has been investigated and reported upon unfavorably by scientific commissions, appointed by the respective governments. On the other hand in France and in parts of Russia it has the approval of official or quasi-official authority. It is however open to the fatal objection that even should it prove efficacious, the expense entailed in systematic protection by this method is in excess of the benefits to be obtained. This has been well demonstrated by Baermann for Bavaria and Württemberg, and Hahn for the whole of Germany. Thus, assuming the necessity of installing one cannon per square kilometer, the cost of a complete installation for Bavaria would amount to $7,500,000, and the annual cost of operating would be about $1,750,000.

In the absence of any practical method of actually averting the destructive effects of hail, the agricultural population must look to insurance to mitigate the loss to the individual sufferer. At the present time however hail insurance, although as stated above has been practised for over a century, is founded upon a far from secure basis of information. Statistics of the distribution of hailstorms in space and time, and of the damage inflicted thereby, are systematically collected from year to year in but few countries. For the most part, the companies have been obliged to gather their own information as best they could; and doubtless, in the legitimate desire to protect themselves having regard to the uncertainty of the data available, they have as a rule imposed higher premiums than would be justified if accurate information were at hand. That the aggregate loss due to atmospheric visitations of this class is exceedingly heavy is well known. Thus it is stated that during the year 1907, in the kingdom of Württemberg, a total area of 43,427 hectares—8.7 per cent of the cultivable land of the country—was ravaged by hail, the damage amounting to over $4,750,000. In the last forty years the loss to agriculturists from this cause in the grand duchy of Baden has aggregated $25,000,000. The annual loss for the whole of Germany is estimated at between 70,000,000 and 80,000,000 marks (i. e., from $17,000,000 to $20,000,000). The annual loss in France is about the same. In Italy it amounts to $12,000,000, according to a recent estimate. These enormous losses do not affect the agricultural class alone. In many cases the national revenues are seriously curtailed from this cause, as it is found necessary to remit a portion of the taxes in the regions afflicted.

The first steps toward improving the organization of hail insurance and extending its benefits to all countries have been taken during the past year by the International Institute of Agriculture. At a meeting of the permanent committee of the Institute, November 24th, 1910, the Bureau of Economic and Social Institutions was charged with the task of drawing up a complete report on the present situation of this form of insurance in the several countries. The report, prepared by Dr. Giuseppe Rocca, has now been published,* and is a most useful contribution to a subject the literature of which is at present extremely meager. Dr. Rocca gives statistics of the companies engaged in the business of hail insurance in Germany, Austria, France, Hungary, Italy, and Switzerland; the laws bearing on the subject in those countries, the technique of this class of insurance; and finally a number of suggestions looking to a uniform system of gathering information of damage by hail and to uniform legislation.

This report was submitted to the Institute at its recent general meeting, and recommendations based thereon will be transmitted to the several governments.

As the recommendations of the Institute will probably lead to the organization of hail insurance companies in this country it may interest some of our readers to know that a number of books has been published in Germany for the guidance of persons engaged in the task of assessing the damage due to hail. A list of them will be found at the end of the article "Hagelversicherung" in Meyers Grosses Konversations-Lexikon, sixth edition.

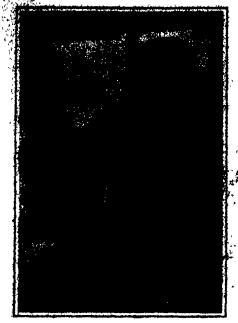
THE FAILURE OF THE AUSTIN DAM

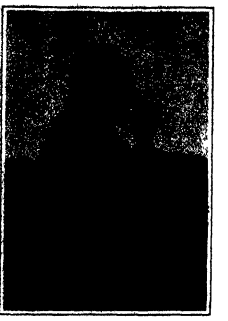
The Colors of the Earth

THE two great elements of difference in the same landscape in winter and summer are, of course, the presence of snow in winter and of leaves and grass in summer. If we could look at our globe from the moon the variation in its aspect due to seasonal changes would perhaps be even more striking than it appears to those on the surface.



In fact, we sometimes lose sight of the very important part which vegetation plays in giving color to what might be termed the countenance of the planet.

It is not the higher forms of plants that always produce the greatest effect in this way. Some of the most striking scenes upon the earth owe their characteristic features to mosses and lichens. The famous "crimson cliffs" of Greenland which extend for miles northward from Cape York, derive their splendid color from the growth of red lichen that covers their faces.



The cliffs rise between seventeen hundred and two thousand feet straight from the water's edge, and being composed of gray granite, their aspect would be entirely different from what it is but for the presence of the lichen.

The rocky pass called the Golden Gate in the Yellowstone National Park owes its rich color and its name to the yellow lichen covering its lofty walls; and the indescribable hues of the great hot-spring terraces arise mainly from the presence of minute plants flourishing in the water that overflows them. Considered as a whole, the vegetation of a planet may give it a characteristic aspect as viewed from space. That its broad expanse of forest and prairie land causes the earth to reflect a considerable quantity of green light to its neighbors is indicated by the fact that at the time of the new moon a greenish tint has been detected overspreading that part of the lunar surface which is then illuminated only by light from the earth.

Morane, the former Blériot pilot, who has invented an exceedingly fast and efficient monoplane.

The Business Side of Aviation

The Money in Flights and Machines

IT SEEMS at first glance somewhat premature to rank the new art of flying among the accepted and recognised branches of industry; but on close examination of the actual state of aviation affairs at present there is found ample reason for doing so.

In the past three years an astonishingly large field of commercial and business activity has been built up, that has to do solely with aeronautics.

There are few who have stopped to realise the suggestive fact that more than half a million men are now actively engaged in some industrial enterprise that has to do with navigation of the air.

To fully appreciate the significance of the commercial side of aviation, a knowledge, or at least an acquaintance, must be had with demands on a flying machine, its uses and the commodities whose manufacture, sale or exchange constitute "the trade."

Aeroplanes at present are used in three distinct ways—for sport or convenience, in war or postal service, and as a means of profit in exhibitions, etc.

The use of the aeroplane by sportsmen and its use by individuals or corporations as a convenience, is the field best developed at present, and for which the greatest future is predicted.

The use of aeroplanes in war seems already definitely assured.

Exhibition flying, however, is likely, and in fact has begun to decline, although races if sufficiently exciting are likely to persist.

A great impetus to the use of aeroplanes by sportsmen is bound to come soon, with the further perfecting of the hydro-aeroplane

The Trade.

The market for aeroplanes is of considerable magnitude, as indicated by the volume of sales made by the various companies. M. Blériot has sold several hundred aeroplanes since the spring of 1909, when he first began manufacturing them on a large scale He has almost been outdone by the Voisins and Henri Farman, while the enterprise of Esnault-Pelterie, Sommer, Breguet, Nieuport, and a score of other constructors in France brings the total of actual sales to a surprisingly large figure.

A single-seater Blériot monoplane costs $4,000 francs, and a two-seater, 28,000 francs This is also the price of Voisin biplanes. A Breguet biplane costs about $6,000 and an Antoinette monoplane is even more expensive.

In general, the range of prices in France is from 15,000 to 30,000 francs.

In England the cost of "all-British" machines like the Valkyrie and Howard Wright runs from $1,500 upward, the price of English made machines being much lower than for those of foreign make

In the United States there are not over a dozen large and established manufacturing firms, with the Wright, Curtiss and Burgess companies as recognized leaders. The Burgess Co has sold more than thirty machines, the Wright Co. two or three times as many, and the Curtiss firm also a considerable number The average price of American machines is $5,000, although the Burgess Co charges $7,500 for a biplane of the Wright type equipped with a Gnome motor. The sales here are at present much less than abroad

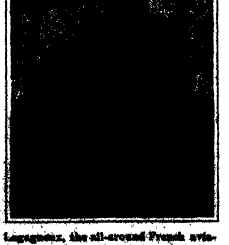
It may be conservatively estimated that the sales of aeroplanes to date, both here and abroad, amounts to about 1,500 Placing the average price paid for these machines at $5,000, it becomes evident that the volume of business is represented by an outlay of well over $7,000,000.

In England, for example, the import trade from January to August, 1911, is represented by $177,000, and the export trade by $70,000, thus giving an insight into the magnitude of the trade between England and foreign countries The exports of France and the imports of America are greater, all statistics proving that France leads the world in the aeroplane industry

The Blériot factory employs about 600 men, and is replete with the most up-to-date facilities The Wright Company has an equally efficient plant of modern buildings, shops and assembly rooms In fact the growth of most aeroplane factories has been phenomenal, and yet the real lasting market for the aeroplane has been but slightly reached

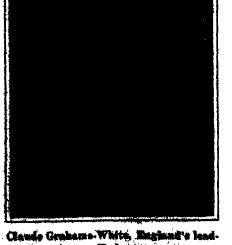
Greater even than the trade in aeroplaning, as a unit, has been the activity in the supply and demand for aeroplane accessories from motors and propellers to the minutest parts of metal or wood

There are fifty or more established firms in this country alone, doing a large business in parts of aeroplanes, like ribs, struts, joints, etc As in France, propellers are being designed and manufactured by more than ten firms devoted to this alone



In France the Chauviere Company is a large corporation employing many hundred men, with extensive shops, and turning out countless propellers for all types of aircraft

Many of these separately manufactured parts never get to be used in a full fledged aeroplane, but serve merely for purposes of experiment



The motor trade is also large, especially in France The Gnome company pays dividends that few "industrials" ever reach, and its business grows apace Many American motors are showing excellent qualities and are much preferred here to the higher priced foreign motors

Aeroplane supply houses abroad have ceased to be

MIDSUMMER MADNESS IN AEROPLANE DESIGNS

A Chamber of Horrors

Wild Designs in Flying Machines

By Marius C. Krarup

EVERY one of the aviation machines shown in the accompanying illustrations is dear to its maker or designer and to his friends Every one of them has something in its construction which is promising, sensible or brilliant to men whose ability in the ordinary walks of life has been sufficient to enable them to save or borrow the money wherewith to substantiate their faith in aviation All but one are proudly photographed, ready to fly at the word "go" Yet only the one not so pictured ever made a start The others probably still cherish the convictions which created them by means of occult or theoretical qualities, the nature of which the uninitiated beholder may only surmise Here is a problem for the psychologist to solve Mechanics alone scarcely furnish the key to its correct solution The shrewd observation that it is better to get into the "game of aviation" wrong than not to get into it at all in its beginning may have shaped many of the hasty creations which abound in the shops of amateur aviators the world over They are evidence of a widespread desire to become identified at almost any cost with a movement clearly destined to be more conspicuously picturesque in its unfolding than any other which civilization has ever witnessed, and prodigiously fruitful in physical, scientific and financial adventure. These odd structures are claims staked off on the hills of golden promise, and the cheerful prospectors confidently expect to "grow up with the country," and to reap the rewards which come to all sturdy pioneers A single unproportioned thought, "given his art" contrary to the advice of Polonius and embodied in steel, wood and fabric, is boldly offered as the entry fee, and lo! the world generously accepts it For is it not after all proof of courage and energy, those primary traits of character which are as much needed for progress as mere insight, which grows with what it feeds upon and may be acquired These men shall have free passes to glory and advancement provided they stand by their claims, work them and guide their next steps a little more closely to the sum total of dry facts and experiences from which real flying aeroplanes have been evolved.

The unproportioned thoughts manifested in the various machines are not without interest The edgewise tumble has haunted the maker of No 1. Of this he is sure So long as the motor and propeller are kept working, these drums will uphold whatever they are capable of upholding, whether the wind tosses them to one side or the other Pivoted as they are to the elegant trussed frame, they afford means for sustentation, for steering and for fore-and-aft balancing, all combined in a single mechanical conception. If the propellers cease propelling, simply tilt both drums forward for a gradual descent Should the impact with the earth be a little hard, the structure offers the same advantage which has served Latham so well in his Antoinette flier, namely, that there is much material to be broken before the shock reaches the aviator's person. It seems almost a pity that the laws of the atmosphere will not permit drums to act as efficient aeroplane lifters

The machine shown in Fig. 2 is the contribution of the Marquis d'Equevilley. It may be imagined that the scion of a noble house has started his train of thought with a profound respect for the magic strength of a bicycle wheel By developing its great principle of centripetal stresses it should be possible to produce a very light framework rich in capacity for areas, strong and yet deformable at its ovalized periphery, and, Eureka! with motor and aviator centrally located and applying the vital forces of propulsion and control from the rigid hub, the very deformation of the rim and planes might be utilized for steering and balancing. Note also the forethought evinced in shaping the upper planes with a self-righting curvature.

If two planes are better than one, then three planes are better than two. This is the simple and powerful idea embodied in the apparatus pictured in Fig. 3, and which is known as the Bousson-Bourgnis. It is common to many triplanes. In addition, an abundance of rudders, generous in size, and a certain flabby flexibility in all the areas, testify to an active, energetic misunderstanding of nearly all the leading principles in successful aviation. The head-on resistance is enormous. What might perhaps have been gained by using perfectly elastic materials shaped and proportioned so as to return an equivalent in work for the power expended in bending the planes back, is squandered through the acceptance instead of unresponsive materials, endowed with an inert flexibility rather than resiliency, the bending of which, under the influence of air resistance, means mainly the generation of heat from molecular friction and the consequent wasting of the power employed for overcoming the air resistance

Stoeckel's monoplane (Fig 6 in this series) was expected to work a revolution in aeroplane dynamics, for it is equipped with a motor of only twelve horsepower driving two propellers of very modest diameters located far below the level of the planes and the bulk of the air resistance. Under these circumstances the machine should immediately tip over backward the moment the wheels leave the ground, but the designer has placed an inverted canoe, also useful as a sunshade, lengthwise over the central portion of his machine, and in this device he must have anticipated special virtues, not only the feeble merits of an underaired parachute, but something extraordinary in the way of balancing effect, since it is otherwise an axiom among aeroplane builders that the power and the air resistance must be kept pretty well in line. As a wind wagon skipping nimbly over the aviation field the compact Stoeckel, with its short wheelbase, should have real merit, however, not to be equaled for meets, particularly if the inverted canoe, as the illustration suggests, may be tipped and utilized to preserve the balance.

The largest aeroplane in the world is shown in Fig. 5. It was constructed at Dunstall, near Wolverhampton, by Lieut. Seddon of the British navy. It is equipped with two 80 horse-power engines and its planes measure an area of 1,600 square feet. The boldness of the figure and of the mechanical execution, with the great loops and sweeping curves suggesting the expert in Spencerian handwriting, almost disarms criticism, punishing it with the query: Can this be possible? Can this be what we are striving for and

what we are coming to! In that case, would it not be better to leave aviation alone until a more advanced mastery of materials shall have made it possible to accomplish it by simpler designs? The large hoops, covered with ribbed like them and tied at the crossings, give great freedom in restoring any desired relation between the planes. By mere changes in the angles and the points of contact of the hoops, practically the same framework may be utilized for a number of experimental variations, and perhaps it may be assumed that the designer has been actuated by this consideration, knowing that the tandem arrangement of planes has been found unfavorable to equilibrium, but knowing also that no large aeroplane construction can be expected until this difficulty shall have been experimentally overcome. But the design looks more theoretical than inspired.

The engineer responsible for the example in Fig. 7 has also tackled elongated construction, being plainly actuated by hopes of escaping from the problem of lateral equilibrium. As for the necessary sustentation, there this scow being sucked forward through the atmosphere at great speed by the innocent little propeller, and the friendly mind will readily perceive how the bow will throw powerful air waves upward against the flying-fox membrane extending from the gunwale, fairly lifting the structure; and, moreover, the hollow of the scow will create a vacuum—the vacuum being a highly favored phenomenon among independent aeroplane designers, nearly always produced without special expenditure of power—to fill which a mighty upward pressure from the atmosphere underneath will automatically assert itself. The hand wheel in front of the operator seems to connect with a simple rudder at the top for side steering, and the perfect lateral balance produced by the narrow conformation and the low center of gravity (really permissible with this shape) should render all other and auxiliary steering means superfluous. For up-and-down steering perhaps the aviator slides his own weight forward and backward.

The seven machines mentioned and illustrated in the foregoing might have been proposed and built whether Lilienthal, Maxim, Langley, the Wrights and Blériot had ever gathered data for aviation or not. But on the Dlapason monoplane (Fig. 4) the eye may rest in peace. As compared with standard design, its variations are more conspicuous than radical. The tail and side-steering apparatus have been cut in twain and moved to the two sides; the *ailerons* have been moved rearward. The arrangement makes room for a large propeller, and, while the equilibrium seems more sensitive, the means for maintaining it and for steering may at the same time have been improved. The machine is said to have flown with some success, and it would be rash to assert its superiority or inferiority in comparison with other models depending on control by rudder action. It accentuates this feature, making even stronger demands upon the aviator's agility than the standard type.

Recent Aeroplane Accidents

DURING the past month there have been many accidents. In several of these the aeroplane has caught fire in the air, and the aviator has been burned to death or killed by the fall. One such accident occurred in France on September 2nd, another in Spain two days later, and the third, in which two men were killed, happened in Germany on the 7th ult. Maron, the French pilot of the Savary biplane, was the first victim of this type of accident. He experienced a bad fall on the 2nd ult. His machine caught fire, and when it struck the ground, he was incinerated under the débris. Lieut. de Grailly, of the French army, also fell and was burned to death on the 2nd inst., owing, it is claimed, to the breaking of a wing of his R. E. P. monoplane. Capt. Camine, with the same make of machine, was killed by the fall due to the same cause. On September 5th, M. Leforestier, a French aviator, fell to his death at Huelva, Spain. His machine, which was of his own construction, is said to have caught fire in the air.

Two other men who were victims of this kind of accident were Lieut. Newmann, a German military aviator, and M. Leconte, his passenger. While making a cross-country flight on September 7th the machine caught fire when at a height of sixty feet, and fell to the ground, instantly killing both aviators. The same day, Paul Senge, another German aviator, fell and fractured his skull at the town of Karlsruhe.

Two days later Herr Eyring was killed near Stuttgart. On September 29th, Capt. Englehardt, Germany's premier military pilot and the first man whom the Wrights taught to fly in that country, was killed by a fall, while his passenger, Herr Sedlmayer, had his skull fractured and received other serious injuries.

In England, Lieut. Cammell, a seasoned Blériot pilot, on the 18th ult., fell to his death while making his first flight in a Valkyrie (English) monoplane. He had been aloft 10 minutes and was making his second wide circuit when the monoplane turned over and dropped 90 feet to the ground. Capt. J. J. Frisble, Louis Rosenbaum and Cromwell Dixon were killed in America when flying at State fairs. The last-named aviator, a youth of but 19, fell 80 feet into a stone quarry at Spokane, Wash., on October 2nd, owing to his turning too sharply to avoid hitting some telegraph wires, and sliding down on end as a consequence. A few days before at Helena, Mont., Dixon had flown over the Rocky Mountains to Blossburg, a small town 18 miles away, and back again. Blossburg lies in a deep pocket in the mountains, from which wild ducks and geese escape with difficulty after battling with the air currents sometimes for hours. It took Dixon twice as long—22 minutes—to attain the necessary altitude of 7,000 feet at Blossburg as it did at Helena. The trip out and back across the 6,200-foot Mullins Pass was made in 15 and 17 minutes respectively. Dixon was given a $10,000 purse made up by several men who witnessed his flight. He delivered a letter from Governor Norris. This is the second time a Curtiss biplane has crossed the Rockies. Ely was the first to accomplish this feat at Butte, Mont., last spring.

On September 25th, at the Nassau Boulevard meet, Dr. Clark, a trick bicyclist, had a fatal fall in a Queen monoplane. He was unable to accustom himself to moving the warping control lever outward instead of inward when turning. A sharp turn to the right, caused by improper warping, resulted in the instant development of gyroscopic force by the revolving motor sufficient to make the machine dive vertically to the ground.

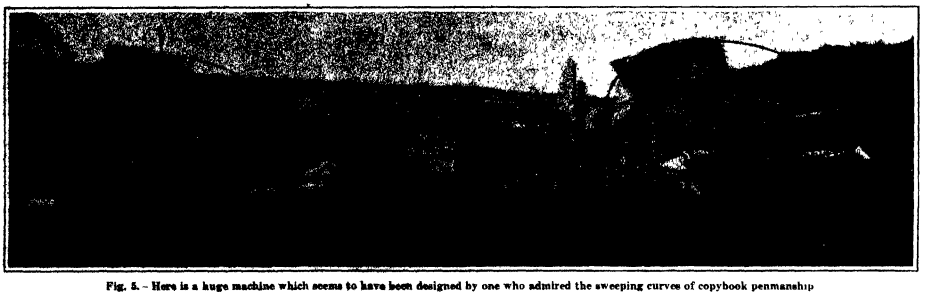

Fig. 5.—Here is a huge machine which seems to have been designed by one who admired the sweeping curves of copybook penmanship.

Progress in Aerodynamics

Studying the Aeroplane in the Laboratory

By Grover Cleveland Loening, Author of "Monoplanes and Biplanes"

IT is the precise methods of engineering that will eventually place flying on a successfully commercial basis As in all other branches of engineering, the theorists and the physicists point the way and give the methods that lead the practical man to the definite solution of perplexing problems, and in this aviation differs in no respect from any other art or science

The determination of the fundamental characteristics of air flow and air pressure on different kinds of surfaces and forms has led without doubt to a quicker and surer success in actual aeroplane flight, but it is qualitative rather than quantitative results that have been obtained so far

Up to the present few if any experiments in measuring the actual values of pressures on surfaces have been conducted on full-sized aeroplanes The results that have been obtained come chiefly from extensive indoor laboratory experiments conducted on planes and shapes of small size, often only one-thousandth of the size of planes used on successful machines

But these small-scale experiments have in most cases been performed with great care and refinement, and from their results there are established the following empirical and fundamentally important laws and equations

A. Any air pressure on any plane or shape varies within the range of speed used in flight, substantially as the square of the velocity, and directly as the size of the surface For the simplest case, a flat plane placed normal to the air stream, the air pressure P may be expressed as

$$P = K\,S\,V^2$$

where S = the surface area, V = the velocity of the moving air against the fixed surface or conversely of the moving surface against the still air, and K = a numerical constant, the most probable value of which is 0 003, when S is expressed in square feet and V in miles per hour

This is an empirical relation, derived from the results of many experiments, and upon it is based practically all of the theory of aerodynamics that finds application in actual practice

B Air passing a surface, or conversely a surface moving through air, causes a frictional drag on the surface, which varies almost as the square of the velocity and directly as the length of the surface

Many formulæ have been proposed, some based on experimental data and some on theoretical conclusions, but they differ widely from one another, and the value of this "skin friction" is still a subject of controversy, many experts claiming that friction is negligible, many others that it is of considerable value Here is a branch of aerodynamics still open to investigation, although the excellent results of Prof. Zahm seem almost conclusive evidence of the large value of frictional resistance.

C The pressure on an inclined flat plane varies with the angle of inclination to the air stream, but bears a fixed relation to the pressure on the same plane, when placed normal to the air stream If we let P = normal pressure, and P^1 = pressure acting on a plane when it is inclined below normal, at an angle a above the horizontal, then we may express this fixed relation between P and P^1 as

$$P^1 = P\,\frac{2\sin a}{1+\sin^2 a}$$

This is known as Duchemin's formula, and has been verified again and again by actual laboratory experiments on small flat planes. A very simple approximate relation suggested by Eiffel is

$$P^1 = P - \frac{a}{30}$$

The normal pressure P may be determined for any plane at any velocity by the relation of $P = KSV^2$, this pressure being gradually reduced as the plane is inclined to a value P^1, corresponding to that angle of inclination.

D. The pressure on arched planes is much greater than on flat planes, and may be equated to the value of the pressure on a flat plane of larger area Whereas in inclined flat planes the pressure P^1 is always perpendicular to the plane, on inclined curved planes at low angles P^1 is inclined in front of the perpendicular to the chord of the plane.

Unlike flat planes, the pressures on curved planes cannot be reduced to intelligible formulæ, and therefore in order to determine the pressures on curved inclined planes, resort must be had to tables of air pressures obtained from actual measurements on test surfaces and not to any formulæ based on such measurements The pressure P^1 on curved planes is usually tabulated as some percentage of the normal pressure P. It is in the determination of the pressures on curved surfaces that the results of aerodynamical experiments on small surfaces have been of most use in aeroplane designing. Lilienthal, Wright, Prandtl, Eiffel, Maxim and Stanton have all made determinations for curved planes that have found much practical application.

E. On curved planes, as well as on flat planes, the total pressure P^1 acting on the plane when the latter is inclined at an angle a, may be resolved into a vertical component L and a horizontal component D. The component L is called the "lift," and is equal to the weight of the aeroplane, while D is called the "drift," and is the dynamic resistance to motion overcome by the thrust of the propeller.

F. On curved planes, as the depth or amount of curvature or arching is increased, the drift resistance increases In other words, flatter planes have less resistance than more highly arched ones. The experimental results of Prof. Prandtl of Göttingen are particularly definite on this point.

G On curved planes, as the aspect ratio or ratio of span of plane to chord is increased, the lift increases greatly for the same area. Both Eiffel and Prandtl have amply verified this.

H. Experiments show that on a plane there exists a point at which all the pressures on the plane may be considered as concentrated without disturbing the equilibrium. This center of action of the forces is called the "center of pressure." On flat planes the center of pressure moves steadily forward from the center of the plane to a point near the front edge as the plane is inclined from the normal or 90-degree position to 0 degree. On curved planes a totally different action is observed. The center of pressure moves steadily forward from the center of figure to a point about one-third the width of plane from the front edge, as the inclination is reduced from 90 degrees to 15 degrees, but at this point it turns abruptly and moves rapidly to the rear, passing the center of figure at about 5 degrees.

I. Experiments in aerodynamic laboratories have further enabled forms of least resistance to motion to be determined and show what kind of torpedo or fusiform

Apparatus recently used in France for testing large surfaces in the open air.

shows give the least disturbance of the air streams.

K. In addition, experiments on propellers have added immensely to the knowledge on this branch of aerodynamics, and have enabled air propellers to be designed that give a higher efficiency than is obtained in marine practice. The great French propeller manufacturing companies have had elaborate experiments conducted on full-size propellers, and have used the results to great advantage.

L. The experimental photographing of the action of air streams on different planes and shapes has been a valuable contribution to aerodynamics and holds promise of becoming a field of much larger scope within a few years.

These are fundamental "quantitative" results.

In many cases the values of different experimenters for the same thing show wide variations. In determinations of the constant *K*, for example, various values from 0.003 to 0.004 are obtained, and many other differences are found. The "quantitative" results of experiments in aerodynamics are as yet not fixed, and it must be conceded that until reliable numerical values are obtained the precise engineering design that is looked forward to is hardly possible, even though excellent approximations may be made.

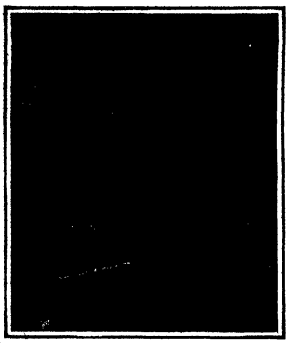
The chief sources of error or difference in the experiments conducted thus far appear to be in the method and size of planes used. Whether size of surfaces has any effect on the nature of the pressures or their unit values is a problem in aerodynamics that is still to be solved. Many claim that the majority of experiments have been conducted on such small test surfaces that their results are of little value. Like all other aerodynamical problems, the answer is to be found in experiment only.

There are five different methods of conducting experiments on test surfaces or models. These are:

1. Dropping the surface from a height in open air or in a closed room. M. Eiffel conducted a series of experiments on the Eiffel Tower in 1905, in which he allowed the test surfaces to fall about 300 feet. Lilienthal made some use of this method in the open air, and at the Russian Aerodynamic Institute of Koutschino, built by M. Riabouchinsky of Moscow, it has been employed.

2. Attaching the surface to a carriage moved on rails, as done by Prof. Prandtl at Frankfort, or sliding down a long inclined railway, as performed by M. Canovetti in Italy.

3. Mounting the surface and testing apparatus on an automobile and driving at high speeds, taking careful record of the pressures. This method was employed to great advantage by M. Eanault-Pelterie some years ago in France.



4. By means of a "whirling table" or large rotating arm, at the outer end of which are carried the forms and planes to be tested. The first aerodynamic testing apparatus, the old 8-foot whirling arm of Rouse used in 1758, was of this type. Later Langley, Maxim, Renard and Lilienthal used it to determine pressures on planes, and to test propellers. The huge new Vickers-Maxim testing table is the latest device of this kind.

5. By a wind tunnel. There are three main kinds of wind tunnels. In the first, used by Eiffel, Prandtl and Maxim, a huge fan blows air into a restricted passageway, and the air is then conducted through various screens and chambers until it issues out past the test surfaces in a more or less uniform steady current. At Göttingen the elaborate character of the air passageway and screens renders the air stream practically perfect in its evenness of flow as it passes the test planes. In the second type of wind tunnel the air is drawn in past the test surfaces by a powerful fan placed in back of them. This is designed to avoid the "churned" air that is exhausted from a fan or propeller. Dr. Stanton in England and Prof. Zahm in this country use wind tunnels of this type. The third type consists of a fan blowing air through a chamber and screens as before, but at the end of the chamber is a nozzle which contracts the air stream and greatly increases its velocity. M. Ratsun has used a wind tunnel of this type in his laboratory in Paris.

The actual devices for measuring the pressure vary greatly with the different experimenters, and this plays, no doubt, an important part in the variations observed in their results. Pressure gages, often inclosures, hydraulic apparatus, aerodynamic balances of great sensitiveness, pendulum devices capable of easy exact calibration, graphical records on cylinders for movable pointers, electrical contact devices and comparison systems with standard flat planes, are some of the many means employed.

To measure the actual velocity of the air stream, anemometers are used, and are either of the rotary cup type, recording on dials, or of the pressure type, in which the pressure of a surface acts through a spring and operates a large pointer.

Only recently the great differences between conditions of air pressure and air flow inside a room and out in the open air have been recognized. The air in a closed room is perfectly quiet and lacks the characteristics of turbulent motion of the open air, characteristics that very likely have much to do with pressures on a surface of an aeroplane. Although a simple means of determining air pressures, the wind tunnel resembles only slightly actual free flight conditions, and many of the results obtained by this method of experiment are seriously open to question.

Eiffel's laboratory. General view of the blower opening in front of which the test planes are mounted.

Scale model of the Nieuport monoplane, experimented with by Eiffel.

Whirling arms, if small, or if rotated at too high a velocity, cause the air about them to assume a rotation, and thus render the results of the experiments inexact.

Movement in a straight line in the open air is now recognized as the best means of experiment in aerodynamics, and the one that holds the greatest promise of establishing fully and exactly the great laws of flight.

The next step forward after experiments with small test surfaces has already been taken. M. Eiffel, for the past few months, in his splendidly equipped laboratory at the Champ de Mars, Paris, has been making determinations on reduced reproductions of actual aeroplane types, models equipped with propellers, motors, wheels and all. These experiments, despite their small scale, are the most valuable conducted so far, and have enabled M. Eiffel to lay down many more fundamental laws that have a direct and important bearing on aeroplane work.

One of the most interesting facts he has brought out is that when two identical planes are superimposed as on a biplane, the lift per unit of surface is less than if the same surface is used as a monoplane. These significant results show that as the distance between the planes is increased from 2/3 to 3/3 and to 4/3 of the depth, the corresponding reduction of unit pressure due to placing the two planes one over the other is 85 per cent, 70 per cent and 75 per cent.

M. Eiffel made extensive measurements on model wings of eighteen different aeroplane types, and made especially complete measurements on models of the new R. E. P. and the Nieuport monoplanes. His investigations on the distribution of pressure over a plane show definitely that the pressure at the front edge is very high, much higher than most aeroplane constructors suppose, and that at the rear it is very low, having often a negative value, i. e., the air is pressing on the upper face of the plane instead of the lower face.

Flight is being rapidly advanced and made safe by the instructive experiments of searchers in this new and fascinating science of aerodynamics.

The Moon and the Clouds

IN *Symons's Meteorological Magazine*, July, 1911, Mr William Ellis, F.R.S., discusses the widespread belief that the full moon possesses the faculty of clearing away clouds. This belief, which is expressed in the French proverb, "La lune mange les nuages" ("The moon eats the clouds") was held by Sir John Herschel, Humboldt, and Arago, but it has no foundation in fact.

Many years ago Mr. Ellis tested the question by examining the observations of the amount of cloud made every two hours at the Royal Observatory, Greenwich. Grouping together, during the period discussed, the observations on the five days about full moon, and similarly the five days about new moon, there was found in both cases to be, on the average, a *maximum amount of cloud* in the forenoon, and a minimum amount in the evening. Now, if from any cause there was found to be a greater dispersion of evening cloud under a full moon than at the time of new moon, the evening amount of cloud at full moon should be considerably less than that at new moon, but there was no significant difference, the amount at the time of full moon being slightly greater than at new moon, this giving no support to the supposition of lunar influence to disperse evening cloud.

The same result was arrived at a few years ago, but by a different method, by Rev. S. J. Johnson. He noted the state of the sky at moonrise and at midnight on the day of full moon for fifteen years. Of 186 occasions of full moon, in 126 there was a similar sky when the moon rose and at midnight, in 33 the sky was clearer about midnight than at moonrise, and in 27 the sky was more overcast about midnight, hence he found nothing to support the belief referred to.

The belief is easily explained. There is, on an average, a progressive diminution of cloudiness toward evening—quite regardless of the moon's phase. The physical explanation of this phenomenon need not be given here. It was set forth a few years ago by Dr. W. N. Shaw, in the *Quarterly Journal* of the Royal Meteorological Society. Now, the change from a cloudy to a clear state of the sky is much more likely to be noticed when occurring near full moon, for with no moon the disappearance of the clouds, though making the stars visible, does little to change the general aspect of the evening, while under a full moon the disappearance of the evening cloud changes the whole appearance of nature, and attracts the attention of the most casual observer.

Brightness of the Rising and Setting Sun

CAMILLE FLAMMARION undertakes to answer, in *L'Astronomie*, the following question, proposed to him by a correspondent: Why are our eyes less dazzled by the sun toward sunset than just after sunrise? Is the early morning sun really brighter than the late afternoon sun?

There are two answers; one physiological, the other physical. The retina becomes progressively more sensitive in the dark. A sudden illumination at night dazzles our eyes, whereas the same absolute intensity of light would have much less effect in the daytime. During the day the eye becomes gradually more and more accustomed to the light; in other words, less sensitive to it.

However, the setting sun is probably actually less bright than the rising sun, because of the diminished purity of the atmosphere through which it shines. Solar radiation pumps up an enormous amount of moisture from the earth during the day.

Phases of Science as Other Editors See Them

Open-tube Telescopes

IN an article published in the *American Journal of Science* Mr David Todd discusses certain points in the construction of telescopes and suggests a plan for the building of an open-tube telescope presenting a number of novel interesting features

All telescopes are made up of three parts Object glass, eye piece and some form of rigid mechanical connection between the two Usually this last is a round tube, but there is no reason why it should not take any shape that the exigencies of mechanics or engineering may demand

Many open-tube telescopes have been built Huygens even built one with no tube at all The objective was placed in a counter-balanced cell with universal joint, mounted at the top of a tall pole He

Design for an open-tube telescope.

drew the axis of the objective into approximate line with the axis of the ocular by means of a cord or wire reaching down to the observer on the ground No objective of modern optical excellence could ever be satisfactorily used in this way The four-foot Melbourne reflector designed and built by Thomas Grubb has an open tube of spirally interlacing straps of steel

The optical advantages of great focal length have long been understood To fully avail one's self of these, it becomes necessary, however, to satisfactorily deal with the mechanical problems of appropriately mounting the parts of the telescope In the large instruments of the present day, this problem presents no mean difficulties and Mr Todd starts out with the idea that a suitably designed open-tube telescope would best satisfy all conditions The principal points to be considered in setting to work on the solution of this problem are, first, to build the tube so that its flexure shall be negligible, and, secondly, to mount the weighted tube so that it can be pointed with ease to any part of the sky Mr Todd says

I have begun my projected telescope, not at the end but in the middle, just as a bridge engineer builds a cantilever (See the accompanying illustration)

The basis of its tube is a cubical section or compartment of steel plates, reinforced as in box girder construction so as to be absolutely rigid and unyielding For a telescope 200 feet or 300 feet long, I would build this central cube about 20 feet square. On two opposite sides it is perforated to allow the cone of rays to pass through, and on two other sides of the cube, at right angles to the cone of rays, are attached the circular bed plates of the bearing pins In other words tube and axis are the same in construction as the ordinary type of transit instrument with shortened axis and a minimum distance between the pivots Needless to say, this is the form which, in the evolution of transit and meridian circle, has been found to give minimum flexure.

As we are *per force* restricted to standard commercial forms of structural steel, the two halves of the tube must be built up, not as cones (the ideal form) but as square pyramids As we have rotation about only one axis to deal with, the flexure of the great tube is easy to handle.

It will be apparent that the alt-azimuth type of mounting follows as a necessary consequence of this evolution, and the altitude motion gives no trouble whatever in either design or practical construction; it is only when we reach the azimuth motion that mechanical and engineering difficulties arise, though they are not wholly insuperable ones.

As we go downward from the telescope to the ground, our troubles increase; and they become a maximum when we reach the plane of junction between earth and mounting Let us now consider the method of dealing with this problem.

What we want is an absolutely smooth positive and yet exceedingly easy motion of a huge vertical shaft. In order to meet those requisites, and treating it as a shaft simply, we should extend its length downward, and confine its motion as a journal between two horizontal friction rings, slipping between roller bearings on vertical axes These rings, with perhaps 100 roller bearings for each, 50 outside and 50 inside, should have horizontal wheels or rollers of large diameter, ground to perfect cylinders. These rings are intended to operate only when the telescope is in use in the wind When the air is still, a smoother azimuth motion would be possible if the friction rings are clamped motionless to the concrete well in which the vertical drum revolves

Then I would float the entire structure in either oil or water, leaving only a few hundred pounds of load on a central button or pintle. In this way a clock of minimum power would suffice to drive a maximum load with perfect smoothness. The expanded vertical axis, then, would be a little like the inner tank of a gasometer when at its lowest point. It should be not less than 50 feet in length, or vertical height; and this drum-shaped form would afford an easy interior construction, insuring absolute rigidity of the vertical towers, which might go down through it, as far as thought best No wind could ever topple the structure over, and the open-air telescope would be safely usable on all but the windiest occasions. By lowering the pintle underneath, and pumping out enough of the flotation to allow the drum to settle down to stationary beds, the drum could be rigidly clamped near the top and bottom, so as to withstand securely all stormy weathers when not in use In case of a severe gale, the telescope would be pointed quartering to the wind, observing carriage and tail-piece unshipped, and tube directed to the nadir. Here the objective would be double-housed against the storm, and the cell clamped firmly This would secure both bearings and open-air pyramids against harmful stress due to excessive wind-thrust, as the gale would strike the structure edgewise.

I have not intended in this paper to deal with the solution of any but the most general problems of this proposed telescope All details have, however, been critically worked out, so that an approximate estimate of cost is available. A 5-foot objective would cost about $25,000, and the entire instrument would represent about double that amount For instance, the weather protection of objective and eyepieces, of altitude bearings and of altitude clamp, quick motion and slow motion; also electric motors for operating the same in both coördinates, and for the requisite variable clock-motion in both altitude and azimuth, as well as for driving the rotary tail-piece on a ball-race. With this arrangement, and an adaptation of Prof. Ritchey's double-slide plateholder with independent rotary motion, micrometric work and even precision photography might be quite practicable All the clamps and motions and clocks may be controlled by electric motors operated from triplicate switchboards in (1) the observing box, (2) the altitude house (not shown on the upright piers), and (3) from the azimuth room concealed beneath the basal drum.

In lieu of observing-chair or rising-floor, observer and assistant ride in a light carriage on the eye-end, swinging on a horizontal ball-bearing axis which passes through the focal plane. This may be wholly inclosed for weather protection, and it can readily be warmed electrically in winter. Should such an instrument ever be erected on a high mountain, as for instance, Fujiyama in Japan, 12,000 feet elevation, where a saddle within the crater provides an ideal location such that wind would rarely shake the telescope, it would be wholly feasible, in fact very easy, to supply the observing box with air artificially compressed to sea-level tension. Thereby we should avoid the disastrous effect of mountain sickness, which not only interferes greatly with one's comfort at elevations much in excess of 10,000 feet, but in consequence of the quickened pulse, tends to shorten the life span of anyone who persists in tarrying long at great elevations, without frequent return to safe and lower altitudes.

An Astronomical Method of Finding an Aeronaut's Position.

WHEN terrestrial objects are invisible, an aeronaut is compelled to employ indirect methods of finding his position. Several such methods have been invented during recent years. Berlingmaier and Marcuse have employed magnetic measurements for this purpose and successful methods of informing an aeronaut of his position by means of wireless telegraphy have been devised. Finally, astronomical methods have been proposed, in which the tedious reduction of the observations is effected by means of special apparatus.

An instrument of this character, invented by Voigt, is shown in Fig 1, and the method of its use is thus

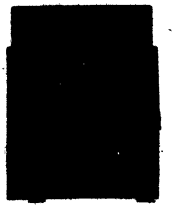

Fig. 1.—Instrument for finding aeronaut's position.

explained in the *Deutsche Zeitschrift fuer Luftschiffahrt*. The principle involved is illustrated by Fig. 2 in which *A* and *B* represent two church steeples rising from a level plain.

If the angle of elevation of the steeple *A*, as viewed from various points of the plain, is measured, we know that all points for which this angle has a certain value α lie on a circle *a* of definite radius, the center of which is the base of the steeple. Similarly, we know that every point at which the angular elevation of the steeple *B* is equal to β must lie on the circle *b*. Hence a point at which the elevation of *A* is α and that of *B* is β must be situated at an intersection of the two circles, i. e., either at *I* or at *II*.

The objects observed from the balloon are not steeples, but stars, and the variation of their apparent altitudes with the balloon's position is due not to absolute distance, but to the curvature of the earth.

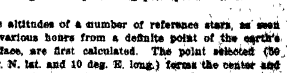

Fig. 2.—Map showing principle involved.

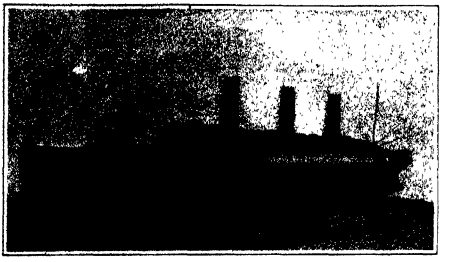
The altitudes of a number of reference stars, as seen at various hours from a definite point of the earth's surface, are first calculated. The point selected (50 deg. N. lat. and 10 deg. E. long.) forms the center and pivot of the revolving map shown in Fig. 1. With the aid of an accurate sidereal clock it is possible to draw the two circles on the map which determine the place of observation by their intersection.



The drawing of the arcs is greatly facilitated by attaching to the map a curve-ruler which can be set accurately to the curvature corresponding to any altitude.

This method, of course, can be employed only at night in clear weather. The principle was employed in 1909 by Dr. A. Brill, who devised an instrument similar to Voigt's.

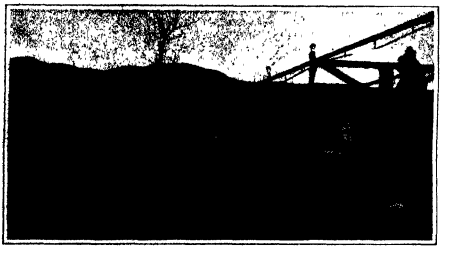
Curiosities of Science and Invention

Model of a Giant Steamship

IN the SCIENTIFIC AMERICAN of December 17th, 1910, we described the "Europa," now under construction for the Hamburg-American Line. This vessel is nearing completion, and in the meantime its name has been changed to "Imperator." A model of this vessel has been constructed, which is particularly interesting from the fact that it is one of the largest and most complete steamship models ever made. It will be recalled that the vessel measures 900 feet in length as against 860 of the "Olympic" and has a beam of 98 feet. It will carry 4,250 passengers, and some idea of this number can be obtained when we consider that the three largest hotels in New York city have a combined capacity of about 3,385 persons. The vessel is unusually commodious. It will contain a Ritz-Carlton restaurant, a grille room, tea garden and even a ratskeller. All of this will be shown in miniature in the 21-foot model. The model will be lighted with miniature electric lights, so that the spacious dining rooms, Roman baths, and other features of the interior may be plainly seen.

Twenty-one-foot model of the giant steamship "Imperator."

Propeller-driven Suspended Trolley Car



WHILE the use of a suspended car is not altogether new, yet the one now being tried out in Burbank, California, is unique in many ways. The chief point of interest is the fact that it is driven by a huge propeller, itself of novel design, which is operated by a 16 horse-power gas engine. The car is no mere toy model, but a fifty-foot structure of steel and aluminium, which has a carrying capacity of 56 passengers. It is built in a torpedo shape, and while the photograph shows the uncovered ribs, the finished car will be covered with a light, flexible covering, with celluloid windows. In addition to the propeller in the rear, another will be placed in the front of the car, doubling its power, and acting as an auxiliary in case of break-down.

The short length of overhead track, about a quarter of a mile, has made it impossible to test the new device for speed, but it operates perfectly, showing that it is no mere theoretical invention. Forty people have been carried with ease at one time.

The six-foot propeller is of great interest, being a radical departure from accepted forms. It will be noted that the two blades are like enormous fans, being formed of sheet metal on ribs of steel tubing. A number of ingenious devices, tilting planes to lighten the car while in motion, apparatus for raising and lowering the car at stations, etc., have been designed to perfect this new vehicle.

Fountain pen for draughtsmen.

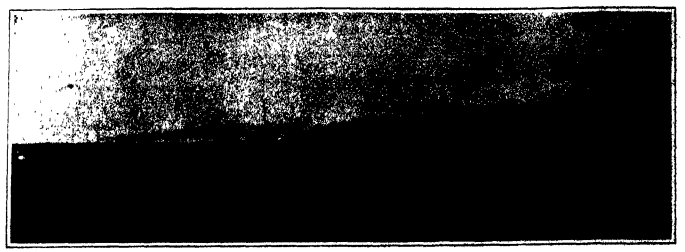
An Aviator's Impromptu Bath

FLYING over water has always had a fascination for aviators, and with most of them the closer they can fly to the surface the better they like it. At the Boston meet last summer H. O. Sopwith, the winner of the $50,000 De Forest prize for the first flight by an English aviator in England across the Channel to the Continent, played leap frog with the motor boats in the harbor, much greatly amused their occupants. He followed this up by performing similar feats with the automobiles on the Boulevard, and when he came across a horse the animal is said to have lain down on the ground in fright. While repeating this performance over water and nearing the bathers at Revere Beach last September, Sopwith, who was accompanied by Harry Horton, fellow aviator, Lea Hammond, met his Waterloo. He was barely skimming the surface and had just risen to a height of 15 or 20 feet in order to fly back over *terra firma*, when his motor stopped and the aeroplane dived into the water. Both aviators jumped and escaped without becoming entangled in the wreckage. The aeroplane stopped bottom side up and completely submerged. Our photograph shows the skids, with their wheels, projecting slightly above the surface. The machine was towed ashore by motor boats. In a few days Sopwith had it fully repaired.

Sopwith's aeroplane submerged after its dive into the sea.

A Fountain Pen for Draughtsmen



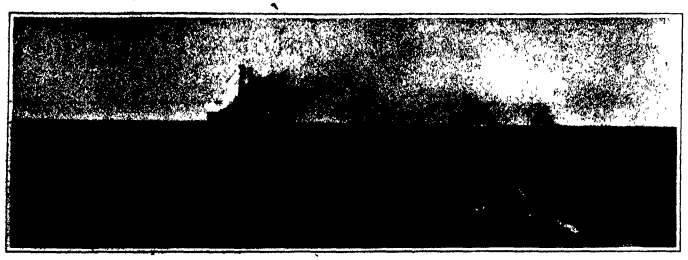
A DETACHABLE container for drawing ink which can be slipped into place on the handle of a draughtsman's pen has been devised by a Los Angeles inventor, and by its use the constant dipping into the ink bottle is obviated. The danger of dropping ink upon the paper is avoided. Likewise. Another advantage is that a number of these containers may be carried in a pocket case, each of them holding a different colored drawing ink, for use in draughting maps, etc. Thus it is possible to dispense with a tray of ink bottles on the table. For filling this device, an ordinary "dropper" is used. As the photograph shows the ink flows from the reservoir through a narrow tube to the pen point, where it supplies an even flow.

Meteorology in American Universities

MR. ANDREW H. PALMER calls attention, in *Science*, to the gratifying increase in the extent to which the science of meteorology is being taught in American universities. Students in medicine, engineering, agriculture and forestry are showing a growing interest in this subject, which until recently was conspicuous by its absence from nearly all university curricula.

At the University of Minnesota instruction in meteorology was first given four years ago. Last year the classes in this subject, under Prof. E. M. Lehnerts, numbered eighty-seven students, being the largest in this branch of science in the country. The University of Wisconsin has a separate department of meteorology, under Mr. Eric R. Miller, the official in charge of the U. S. Weather Bureau station at Madison, which is domiciled in one of the university buildings. Three courses are open to undergraduates, and four to both graduates and undergraduates. At the University of Nevada instruction in meteorology will be offered for the first time during the coming college year. The instructor will be Mr. S. P. Fergusson, late of the Blue Hill Observatory. The University of California is also about to inaugurate courses in meteorology and climatology, under Mr. W. G. Reed, Jr., who for some years past has been an assistant under Prof. R. DeC. Ward, of Harvard. The last university offers five courses in climatology and meteorology, one of which, a research course, is given at the Blue Hill Observatory by Prof. A. L. Rotch, the others at the university by Prof. Ward. At Williams College courses in meteorology have been given for several years by Prof. Milham.

There are a number of other universities and colleges, not mentioned by Mr. Palmer, at which brief courses in meteorology are given by local officials of the United States Weather Bureau, among them being the Universities of Missouri, Ohio, Tennessee, Nebraska, and Washington, Cornell University, Norwich University, and Drury College. At still other universities and colleges the officials of this bureau give frequent or occasional lectures. In fact, educational work in meteorology is recognized as one of the regular functions of the Weather Bureau, the personnel of which includes all the professional meteorologists of this country—with a few notable exceptions.



"And so we moved majestically out of Hampton Roads. As the flagship drew away, the vessels, in divisions of four, swung into line, until the fleet of sixteen battleships was strung out over some four miles of water."

A Landsman's Log ... ship "North ... board the Battle-... akota"—I.

By J. ... Walker

This landsman's log is written by the Editor of ... zine Naval Number to appear early in December ... with the Naval Number issued during the Spanish ... written entirely by prominent officers of the Navy ... The leading article, moreover, will be from the pen ... Navy. The illustrations will consist of special ... practice of the Atlantic Fleet on the Southern ... grounds.

SCIENTIFIC AMERICAN as a preliminary to a magazine will be comparable in its size and completeness ... In one respect it will be unique, for it will be ... a specialist in the particular field that he covers. ... Hon. George von L. Meyer, the Secretary of the ... has taken during the recent maneuvers and target ...

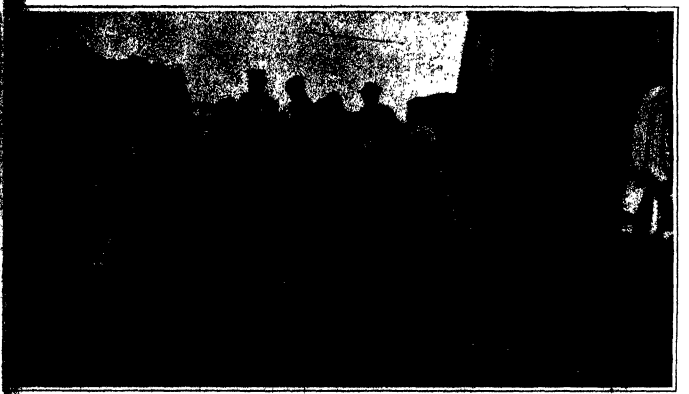
"Anyone who has handled the wheel in ships, big or small, will understand that it is no simple matter to hold sixteen vessels of fifteen to twenty thousand tons in absolutely true line ahead."

IT is a far cry from a battleship, lying peacefully in port and "open to visitors," to a battleship at sea, developing over one million foot-tons of energy per minute as, with a savage roar, she flings some four tons of steel high into the air, to land with amazing accuracy upon a target, dimly discernible in the haze of the far horizon

For many years it has been the aim of the SCIENTIFIC AMERICAN to make clear to the people of the United States, by pen and brush and camera, just what kind of a navy it is that flies our national flag. But photographs and printed statements of length, size and speed, serve, at the best, to give an impression merely material and technical To understand what a battleship actually stands for, she must be studied from within and on the high seas Then it is that the stupendous fabric becomes vibrant with throbbing life, and the inarticulate thought and skill that have been wrought into her at the designer's desk, and in forge and shop and dockyard, speak with many voices.

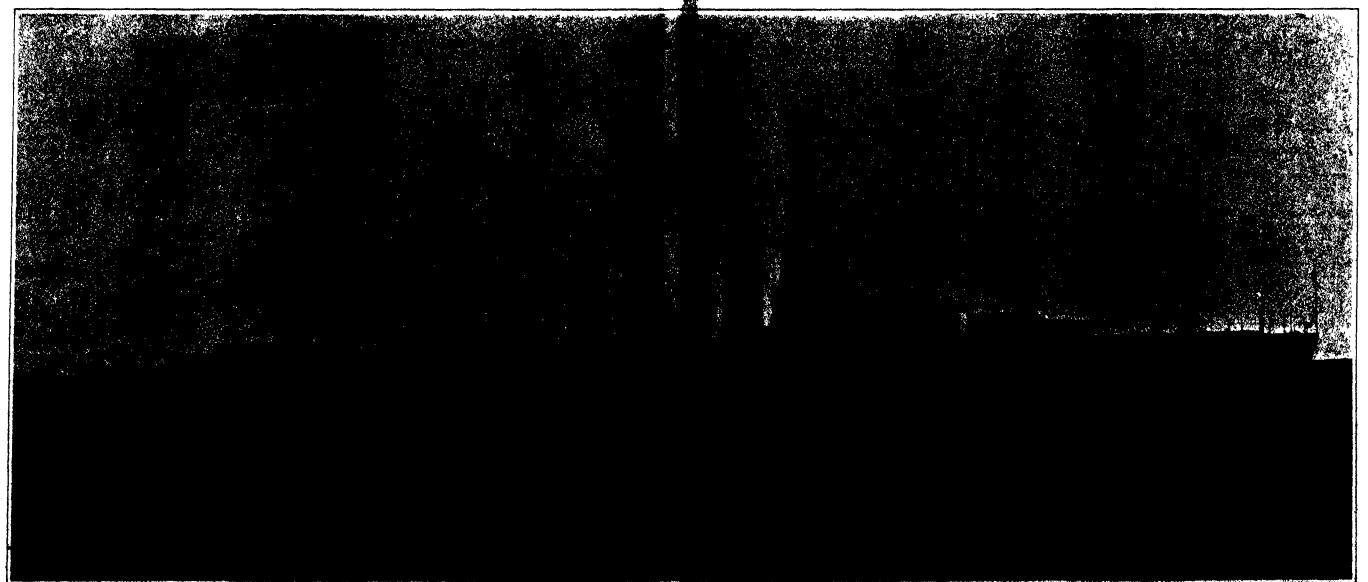
As with the ship, so with the men that man her "All the world loves a"—sailorman, but not all the world can understand him—the essentially human side of his life, the professional enthusiasm, the pride of ship, and his noble devotion to his country and his country's emblem, the flag All this can be grasped only on those rare occasions when, as in the present case, a civilian is privileged, by the courtesy of the Secretary of the Navy, to make the ship at sea his home, sit at mess with its officers; mingle with its men, and absorb the atmosphere—unlike anything ashore—which pervades this highly-organized community of one thousand souls, shut up in its home of steel

At least, so it seemed to the editor as he stepped aboard the particular steam cutter at Old Point Comfort wharf that carried the letters N. D on its bow, and was taken to the gangway of that stately ship, the "North Dakota" The "North Dakota" was one of sixteen battleships that were awaiting the Admiral's signal to weigh anchor and proceed to Tangier Bay in the Chesapeake, there to watch the Delaware (sister to the "North Dakota") shoot away as much as she could of what was left of the old hulk, "San Marcos" ("Texas").



The spacious breadth and long, unobstructed sweep of the main deck of a dreadnought is suggestive rather of an ocean liner than of a ship of war—an impression which is deepened on the "North Dakota" by the yacht-like spotlessness of her deck Here at least we see a survival of one of the traditions of the old three-decker, for the holystone and "washing-down" serve now, as in the days of Paul Jones and Nelson, to keep the man-o'-war'sman busy through many a long hour of the cruise To that distinctively American plan, the center-line placing of the turrets, is due this fine vista of between three and four hundred feet of deck

"Getting under way" is a very different matter from the picturesque confusion, so stirringly described by Marryat and Fenimore Cooper Gone are the coils of rope the rattle of blocks, the creaking yards, the flapping of canvas and the tramp of many feet around the capstan Instead, there is the scarcely audible beat of the capstan engine below decks, and the "chug-clug" of the forty-pound cable links as they come aboard through the hawsepipe and bring the flukes of the 10-ton anchor to their snug resting place under the bows



We are the fourth ship in the first division, with the "Connecticut," flagship of Admiral Osterhaus, in the van From sheer force of habit, I listen for the rhythmical throb of the engines as evidence that we are under way, but it is never felt although a glance at the water shows that we are already moving at 10-knot speed. And then I remember that this ship is turbine-driven, and therefore tremorless as far as engine-room vibration is concerned.

"The spacious breadth and long, unobstructed sweep of the main deck of a dreadnought is suggestive rather of an ocean liner than of a ship of war."

"The holystone and washing down serve now, as in the days of Nelson and Paul Jones, to keep the man-o'-war's man busy through many a long hour of the cruise."

Copyright 1906 by Kathryn Becker

Length, 510 feet; displacement, 20,000 tons; speed, 21 knots. ... Tornado tubes, two 21-inch submerged. Officers and men, 930.

THE "NORTH DAKOTA"—... IN THE UNITED STATES NAVY.

Later I understood why it is that the turret officer and gun-pointer swear by the sweet-running turbine, and become impatient when they learn that Washington is still toying with the reciprocating engine and dreaming of pounds per-horse-power economy For the "North Dakota" was well aware that her sister-ship the "Delaware," with reciprocating engines, was keeping station in that four-mile line of battleships, with forty per cent less consumption of coal than was needed for her own turbines The matter came up for discussion in the wardroom mess "Bear in mind," said one of the engineer officers, "that the 'North Dakota,' by a turn of the throttle and the opening of a few valves in the casing, can at a moment's notice jump her speed from ten to twenty-one knots, and keep going for hours at maximum power, with the same sweet certainty of motion, and without giving her engine-room personnel the least additional anxiety And you know what happens," said he, "when a demand for full power is suddenly rung down from the bridge to the reciprocating engines of a battleship" The turbine has never been able to match the reciprocating engine in coal economy at the low cruising speeds, but when 15 knots has been passed, the difference begins to disappear, and at high speed the latest type of turbine (that of the "North Dakota" is of a rather early design) shows a greatly superior economy

And so we moved majestically out of Hampton Roads As the flagship drew away, the vessels in divisions of four swung into line, until the fleet of sixteen ships was strung out over some four miles of water Five hundred yards from foremast to foremast was the distance, which was maintained by turning the propellers of each ship at the revolutions which had been determined in the standardization trials as correct for a 10-knot speed The distance is also checked by triangulation, the height of the mast of the ship ahead being known and the angle subtended observed by stadimeter In foggy weather each ship follows a towing spar, towed by the ship ahead at the end of a cable of the proper length The speed is shown to the ship astern by cones hoisted on the signal yard half way up for half speed, full up for full speed When a change of speed is made, the cone is shifted accordingly—were it not for this the vessels might overrun each other

Any one who has handled the wheel in ships, big or small, will understand that it is no simple matter to keep sixteen vessels of 15,000 to 20,000 tons in absolutely true line ahead, and hold them so for an hour at a time But it was done so well that, from the taffrail of our ship, all that could be seen was the "New Hampshire," flagship of the division immediately astern, which, except at the changes of course, completely shut from view the three miles of ships beyond No "snakes" are possible here; and when it is remembered that a battleship is generally far more difficult to steer than an ocean liner the excellent work of the quartermasters of the Atlantic fleet will be apparent

In the late afternoon we sighted the partly-sunken "San Marcos"—victim of to-morrow's onslaught—her broken masts and tilted smokestack giving her an appearance more tipsy than tragic Signals flutter from the flagship, and the bits of gaudy bunting serve to scatter our hitherto unbroken line In stately sequence the divisions swing out to port or starboard—the head of the line slows down—there is the crash of falling anchors—and the fleet moves with an accuracy that is, to unaccustomed eyes, truly wonderful, into three parallel lines, and each ship, in its appointed position, is snugly anchored for the night

And then, as the shadows deepen there comes a transformation scene that will not soon be forgotten The forbidding, dark-gray mass of each ship begins to sparkle with myriad incandescent lights, row above

Aeronautic Inventions, Curious and Useful

AERIAL and marine navigation, while in most respects totally unlike, are yet in certain particulars closely analogous, and this is perhaps most clearly observed in considering the smaller auxiliary devices relating to these arts. Although aerial navigation, so far as heavier than air machines is concerned, has only recently been accomplished, the art in a broad sense has been, nevertheless, the subject of patent applications for many years, and a consideration of these patents indicates that not only has inventive genius been active along broad lines of development, but that it has been busily engaged in the perfection of details of construction which now that so great interest has been aroused in the practical side of the art, may be found of great value.

While the first marine anchors were probably crude affairs, consisting of a rock or crooked branch, the art of aerial navigation did not arise until long after marine anchors had reached a fairly high state of development, and aeronautical inventors were thus able to confine their attention largely to the adaptation of these marine anchors to aerial use. Among the first patents granted in this country for an aeronautical device is that to one Bell, dated March 26th, 1850, which among other details shows a water anchor or drag, clearly adapted from marine use, and which, as illustrated in Fig. 1, consists of an umbrella-like structure 2, 3, 4, supported upon a rod 1, the rod being provided with ropes 6 and 8 at its opposite ends. It is evident from the construction shown, that, if the device be immersed in water and attached to the flying machine by the rope 8, the rope 6 being slack, the umbrella structure will remain closed and offer little resistance to travel through the water, while if the rope 6 be pulled taut and rope 8 be slackened, the pressure of the water will open out the umbrella device, thus presenting a large surface to the water and acting as a very effective drag or water anchor. Similar in type, but adapted for land use, is the device shown in the British patent to Alexander of 1893, in which a supporting rod similar to that of Bell's device is provided, but instead of the umbrella structure of the latter, the rod carries a series of backwardly projecting prongs or claws, which, when the rod is towed by one or the other of its ropes, respectively, slide easily over the surface of the ground, or engage with the same and act as a positive anchoring means.

In the year 1854, the Earl of Aldborough, one of the most enthusiastic promotors of aviation of his time, patented in Great Britain a flying machine embodying a multitude of ideas more or less practical, and among his many suggestions, describes an aeronautical anchor of peculiar form, evidently the result of an investigation of the anatomy of a bird's foot, and which he describes in the following terms: "I prefer forming the grapnels with flukes, attached to the stem by joints, and pressed downward by springs in such manner that the flukes shall strike downward when liberated, in a manner bearing a certain resemblance to the talons of a bird, separate cords being attached to each of the flukes, and all these being collected in a small sheath, and so arranged that the flukes can be raised, or permitted to spring downward by either fixing these cords in any convenient way, or letting them go when it is desired that the flukes shall act so as to enter the ground or seize any object." Apparently not satisfied with this device he further perfected it in a patent of somewhat later date wherein he describes a steel-sheathed cable for supporting the anchor, the cable being provided with a device for lessening the effect of sudden shocks, this latter feature being of very common use in marine navigation, being known in that art under the name of "shock-absorbers."

Some curious Aeronautic inventions.

More clearly illustrative of this last feature is a patent to Fiesse, granted May 19th, 1908, which, as seen in Fig. 2, discloses a highly developed form of shock absorber interposed in the anchor rope of a flying machine, wherein the two portions 1 and 2 of the anchor rope are connected with the piston rods 3 and 4, respectively, extending from the pistons 5 and 6, the latter sliding in the cylinder 7, and normally forced toward each other by the compression springs 8 and 9. It is evident from the construction shown, that if the anchor rope be subjected to sudden shock, as by a heavy gust of wind striking the anchored machine, the two pistons will be drawn apart against the action of the springs, thus relieving the rope of the sudden strain.

In the patent to Mackenzie, granted in 1869, is shown an interesting development, wherein the shank of the anchor is provided with a snap-hook, for use, as the inventor states, in place of the anchors when stopping at regular landings, where rings will be provided for their reception. This leads to a brief consideration of aeronautical landing places or stations, and as in many other things aeronautical, the Earl of Aldborough, above quoted, appears to have been the first to make suggestions along this line. Among other things he suggested that such stations be provided with lights and signals for the proper guidance of the aeronaut, which suggestion appears recently to have been carried into effect in European countries. Along this line various patents have been granted, the proper protection of the anchored air ship being in general the main object, the patent to Fechtig, granted in 1910, being, perhaps, characteristic. This patent discloses what in effect is a modified locomotive round-house, having a turntable and radiating sheds, the turntable being inclosed, except at its ends. One of the great difficulties encountered in housing air ships, especially the great dirigibles of the Zeppelin type, has been due to the effect of side winds upon the great expanse of surface, and this the device of Fechtig is intended to obviate, by providing the inclosed turntable which may be presented to any point of the compass for the easy entry of the air ship, and which will protect the same while permitting it to be placed in juxtaposition to its permanent quarters.

A curious device for attaining the same result is that shown in the patent to Gothan, granted in 1910, and which is illustrated in Fig. 3, comprising a balloon shed 1, and a circular platform 2 in front thereof, the platform being provided with a series of vertical openings or jets 3, connected to a supply of compressed air. When these jets are all opened, a circular, vertical wall of air is created, thus effectually shutting out side winds. When it is desired to house a flying machine, the jets are cut off on the side from which the machine approaches, but as soon as the ship has passed through the opening thus formed in the air wall, the jets are again turned on, thus serving to fully protect the ship while being placed in its shed.

While the marine anchor is ordinarily made particularly for use in mud and sticky, soft material, the aeronautical anchor must oftentimes encounter hard, dry ground, and, owing to its necessarily light weight, some modification of the marine anchor must obviously be made if the device is to prove successful. Among the simplest forms of anchor is shown in the patent to Myers, May 20th, 1862, con-

ALCO
Motor Trucks

How to Judge a Motor Truck

BUYING a motor truck is like hiring a man. You are not interested in the color of his eyes, the tilt of his nose, or his height and weight.

You want to know what this man has done and what he can do.

Just so with the motor truck.

It's what a truck will do that interests you.

Price alone sells few trucks. It's what you "get for the money" that sells them. In other words *value*.

Four things determine value in a truck.

One of them is *good design*.

The only sure way to tell good design is by results.

If a truck is not well designed the owner soon knows. If it is well designed, and if he can use more trucks in his business, he buys more of the same make—naturally.

Thus you may judge a truck by the number of repeat orders or re-orders.

In the case of the Alco Truck 62 per cent. were purchased on repeat orders. Nine-tenths of this number are in the service of firms and corporations listed in Bradstreet's at over $1,000,000.

Before purchasing, many of these large firms carried on extensive experiments to determine which motor truck was best. If only *one* Alco had been purchased by each of these concerns, its place among motor trucks would be clear. But each of these bought more than one. The American Express Company has 40; the Gulf Refining Company 10; Gimbel Brothers 18; the Long Island Express Company 10; and so on.

Among many the Alco has been accepted as the standard—all future purchases will be Alcos.

The second point on which value depends is the *experience* of the manufacturer.

Good design means little unless experience in building is back of it. The thing to know is "how long has the manufacturer been building trucks?" "What does the manufacturer know about the problems of transportation?"

For the American Locomotive Company, builders of the Alco Truck, the experience began in 1905. The Alco Truck was marketed in 1908. The experience of the American Locomotive Company in problems of transportation dates back to 1835 as movers of the world's goods.

The problems of the locomotive and the problems of the motor truck are parallel. One is a power driven vehicle running on rails. The other a power driven vehicle running without rails.

The experience of the American Locomotive Company, as builders of the Alco Truck, is rare.

Value is again determined in the *way the truck is built*.

Little does it matter how well a truck is designed if it is not well built. It becomes a consideration of factory and factory equipment.

The Alco factory represents an investment in equipment of over $4,000,000. In it are built 95 per cent. of the parts of the Alco Truck. It has the most complete heat treating plant of any motor truck factory in the world. It has large chemical and physical laboratories to analyze and test the metals that go into the Alco Truck.

In special and automatic machinery the investment is immense—in jigs and tools alone the investment is over $2,000,000. Many of these tools are not tools in the ordinary sense of the word, but are fine instruments—like those of a surgeon—and are kept in flannel when not in use.

In this factory is the largest drop hammer in the world. It weighs 250,000 pounds.

The fourth consideration in determining value—and one that is most decisive—is the *responsibility* of the manufacturer.

The safest thing in the world to buy is reputation. Buying a truck from a manufacturer without reputation or reponsibility is like making a loan without security.

The American Locomotive Company is capitalized at $50,000,000. It dates back to 1835 as movers of the world's goods. It has built 50,000 locomotives. It builds 60 per cent. of all the locomotives in the world. Its reputation is indelible.

These four considerations—Good Design, the Experience of the Manufacturer, Good Building and the Responsibility of the Manufacturer—provide an "acid test" for judging a motor truck.

There are a few trucks that can stand this test.

Of these the Alco Truck is one.

You should investigate the Alco for one vital reason, if for no other: —*latent* experience—of its builders in manufacturing power driven vehicles.

Write for the new catalog.

Your Three Greatest Tire Troubles Ended

No-Rim-Cut Tires

10 Per Cent Oversize

With Double-Thick, Non-Skid Treads

They end rim-cutting forever. They avoid the blowouts due to overloading. They prevent skidding and do away with chains.

These No-Rim-Cut tires, in the past two years, have increased our tire sales by 500 per cent. Over 700,000 have been sold.

These tires now dominate the field. With tens of thousands of motorists they have cut tire bills in two.

Now they come with this ideal Non-Skid tread.

The Final Tire

After 12 years spent in tire making—after ceaseless improvements—we believe that the Goodyear No-Rim-Cut tire is now pretty close to finality.

Our greatest invention—controlled by our patents—has ended rim-cutting forever. That was, perhaps, your chief worry and expense.

By making these tires 10 per cent oversize—without extra charge—we added 25 per cent to the average tire mileage.

By 12 years of tests on tire-testing machines we have brought our formulas and fabrics close to utter perfection.

And now we have added a Non-Skid tread worthy of all the rest.

We never hope to see a much better tire than the Goodyear No-Rim-Cut today.

The Winter Tread

Most of you know the No-Rim-Cut tire—the oversize tire—which has come to such immense popularity.

The control of this tire has thrice trebled our tire sales within two years. The sales to date exceed 700,000 tires. And, to meet the demand, we are increasing our capacity to 3,800 per day.

Since 1906 our experts have worked to create for this tire a perfect Non-Skid tread. Now we have it. We offer you now, for winter use, your highest ideal of a tire.

An Extra Tread

The Non-Skid feature is an extra tread, vulcanized onto our regular tire. Thus the tread is made double-thick.

This extra tread is exceedingly tough, as impervious to wear as a rubber tread ever can be. It remains effective over enormous mileage. When it does wear off there's our regular tread below it.

The tread is made up of deep-cut blocks, which grasp the road surface with countless edges and angles. The blocks widen at the base, so the load is spread over as wide a surface as it is with the smooth-tread tire. The grooves can't fill up.

This double-thick tread, because of its thickness, reduces danger of punctures by 30 per cent.

Chains, as you know, are ruinous to tires. Metal projections, too. Rubber and metal never combine, and their friction soon wrecks a tread. Short, soft projections are temporary. Here is a tread that's immensely efficient, and a tread that endures. And it comes on the tire you are bound to demand when you know the facts about it.

Please look it up. This tire is made for your safety and economy. Learn what it means to you.

GOODYEAR

No-Rim-Cut Tires

Aeronautic Inventions, Curious and Useful

(Concluded from page 343.)

sisting merely of a circle of sharp pegs projecting downwardly from the bottom of the car and converging toward the center, thus when forced into the ground by the weight of the aeronaut, clutching a large section of earth and acting as a powerful anchor. Mr. Barnes, in a patent granted in 1892, has improved upon the above device to the extent of substituting long, corkscrew-like rods for the straight pegs and providing means for revolving these by power from his motor, thus obtaining a tremendous grip upon the ground.

Another form of earth anchor as illustrated in the German patent to Boinet, consists of a hollow shell having a pointed end and adapted to be forced into the ground, the shell being provided near its lower end with openings through which may be projected curved arms which enter the adjacent soil and thus obtain a powerful grip thereon. Similar, but with some modifications in structure, is the device shown in the patent to Thomas, dated July 24th, 1906, and illustrated in Fig. 4, the manner of operation of which is so obvious as to require no explanation. The acme of inventive ingenuity along this line must, however, be conceded to an Englishman, Mr. Jackson, who proposes to attach a cannon to the car of his machine and shoot dart-shaped anchors therefrom into the ground.

Among other interesting devices might be mentioned that shown in a patent to Lake, granted in 1908, in which is shown the car mounted upon three wheels, the two rear wheels being free to swivel in the manner of furniture castors, while the front wheel is provided with long spikes upon its periphery and may be held stationary when desired. When thus held, the spikes project into the ground, thus forming a pivotal point about which the whole structure is free to turn, and thus the machine will always head into the wind after the manner of a weather vane.

A device in which the anchor is put to a seemingly anomalous use is shown in a patent granted to Mueller, in 1909. Here the anchor is not used for the purpose of retaining the machine in a fixed location, but as a means for causing its proper ascent. In this case the anchor is held by an endless cable passing over pulleys on the machine. When about to start, the anchor is firmly embedded in the ground. Upon starting the motor, the machine endeavors to rise, but being restrained by the anchor, describes the arc of a circle about the anchor as a center until the cable becomes so nearly vertical as to release the anchor, when the machine is free to take flight, by this means permitting the machine to rise from its restricted quarters, and to pass over obstructions in its immediate vicinity.

As every well equipped marine vessel is provided with life-preservers and life-boats for use in emergency, so will the flying machine of the future be provided with means for assuring the safety of the aeronaut in case of accident to his machine, and in the provision of such means the inventor has not been idle. The majority of such devices are modifications of the well known parachute, but it is interesting to note the variations in and methods of adapting this simple device for use in connection with other aerial craft.

It is well known that if the gas be suddenly allowed to escape from a balloon when at a great elevation, the balloon envelope will, in many cases, assume of itself, a parachute form within its netting, and fall slowly to the ground. This fact has not been overlooked by the inventor who has endeavored to assure this action by giving the balloon a special form or construction, a typical example of which is seen in the patent to Chanoz, granted in 1906 (see Fig. 5), in which the balloon is of lenticular form, comprising a metal rim 3 to which the car is attached and provided with a set of rigid ribs 6 converging to a central collar 5. The upper and lower sheets of oiled silk forming the gas bag are attached to the rim 3, [illegible] either the upper or lower sheet be accidently ruptured and the gas escape, the material of the bag will be forced by the air pressure against the ribs 6 which will support it in parachute form and thus prevent a precipitous descent.

In a like manner, by taking advantage of a special form of aeroplane, the inventor has converted this type of machine into a more or less effective parachute, as for example in the French patent to Weld (Fig. 6), wherein an end view of the plane is shown. Here the main plane 1 is in the form of a half cylinder, open downwardly and at its ends. The ends of the plane are, however, provided with curtains 3, normally folded, but which may be extended to close the ends of the machine, thus forming a sort of parachute.

Of course only a specific type of aeronautical vehicle lends itself to the above construction, and so independent parachutic devices have been produced. Although the ordinary aeroplane has proved capable under skillful management, of descending safely from great heights without motive power, yet the inventor has made assurance doubly sure by providing the aeroplane with a folding parachute adapted to be spread in case of accident by the air itself, one of the most recent of these devices being that of G. F. Myers, in which the aeroplane consists of a series of super-posed ring-like or annular planes. Upon the upper of these planes lies a normally folded parachute attached by a series of restraining cords to the plane, and being also provided with a controlling cord. By pulling the latter, the parachute is drawn beyond the edge of the plane, permitting entry of air between the plane and parachute, the latter thus being expanded and rising to the full extent of the restraining cords.

The helicopter and flapping wing types of machine, however, seem to offer little chance of safe landing in case of failure of the motor, and as the inventors of this form of machine evidently expect them to go up, so they have, with great unanimity, provided them with parachutes to prevent them from coming down too suddenly, and of these devices, one of the earliest, patented to Quinby, in 1861 (see Fig. 7), is typical. Here the machine, which is of a composite type, having valved, beating wings 1, and helicopter wheels 2, is provided above the latter with a normally folded parachute 3, adapted to spread itself if the machine begins to fall and thus prevent too rapid descent.

While all the above devices have for their object the saving of the entire machine from the effects of a fall, attention has also been given to the provision of parachutes for saving the person of the aviator alone, and typical of such devices is that patented to Griepe in 1907, covering an air ship embodying among other features a trap door in the bottom of the car communicating with a compartment containing a parachute provided with a releasing device, whereby in case of emergency the operator may suspend himself from the parachute and abandon the air ship to its fate.

It is well known that parachutes cannot always be depended upon to open automatically when required, and to ensure their proper opening, M. Pichou has taken out a patent in France covering the device shown in Fig. 8, wherein 1, 2, indicate the frame of the flying machine, 3, 4, a circular connecting member, 5, a circular box resting on 3, 4, the box being provided with a central opening in its bottom, 6 is a receptacle filled with explosive and resting on the bottom of the box 5 and covering the opening, and 7 is a trigger operated by a cord 8 for detonating the explosive contained in the receptacle. Attached to the bottom of the receptacle by cords 9 is the seat 10 for the aeronaut, and attached by cords to the top of the receptacle and normally nested in the box 5 is a parachute provided with cover 11 to prevent the cords from disturbing it. In case of accident, the operator merely pulls the cord 8, thus exploding the charge in the receptacle, which ejects the parachute from the box, when it immediately becomes effective and pulls the aeronaut, seat and all, up through

SWAN SAFETY FOUNTAIN PEN

Possesses features that no other pen can boast of, that lift it high above the rest toward the acme of pen perfection. The "Swan Safety" cannot leak.

The "Gold Top Feed" which shows on the upper face of the nib in the illustration keeps the pen moistened with ink at all times and insures instant writing.

The "Ladder Feed" on the under face of the nib, as the cut illustrates, supplies the ink steadily without skips, blots or overflow of ink.

The "Screw down Cap" is a device that screws down air tight over the nib, forming a vacuum and making it impossible for the pen to leak.

SWAN SAFETY PEN

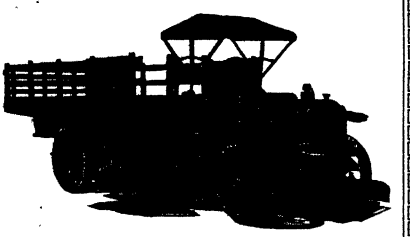
Can be carried in your pocket, suit case or handbag in any position, horizontally or upside down. The "Swan Safety" will never leak.

For sale at all stationers and jewelers. Prices $2.50, $3.50, $4.00, $5.00 and up. We will send illustrated price list on request.

MABIE, TODD & CO.

17 Thames Line 209 S. State St.
NEW YORK CHICAGO
Montreal, Paris, Berlin, London, Sydney

Of course most of the above devices require some preliminary action on the part of the aeronaut in order that the parachute device may become effective, and in order to avoid this a still further arrangement has been devised wherein the parachute forms a part of the clothing of, or is attached directly to the person of the aeronaut. The Earl of Aldborough, before referred to, appears to have been the originator of this idea, and describes a parachute to be worn about the neck and reminding one by its general appearance of the old fashioned neck ruff, but of exaggerated proportions, and provided with stays leading to a belt at the waist. Of a very similar character are the devices patented to Wilke, in Germany, and to Mayer, in Great Britian, illustrated in Figs. 9 and 10, respectively, wherein the former shows a sort of vest embodying the parachute and having stays leading to the wearer's belt, while the latter shows a parachute attached to the aviator's coat and adapted to be folded over the head and shoulders when not in use, thus serving as an additional protection against the weather. A further modification is seen in the patent to Ulmer, January 31st, 1911, which consists of a hat for the aviator, provided with a pocket in which is folded a parachute the cap and parachute being attached by a cord to the aviator's belt. In the event of an accident to the machine, the aviator will immediately remove his hat, when the air current, caused by the descent, will inflate the parachute and the aviator will be saved all further cause for anxiety.



In passing, might be mentioned the device patented to Mr. Oppenheimer in 1879, and illustrated in Fig. 11. Although designated a fire escape, it would appear equally advantageous for aeronautical use, the padded shoes 3 being without doubt a highly desirable feature, especially in the estimation of the luckless pedestrian upon whose head the wanderer from space might chance to descend.

As in the operation of the submarine boat, it is of primary importance that the depth below the surface be always known, so in aeronautics it is of interest to know the height above the earth. Although many devices have been devised for registering the height or the vertical movement of flying machines, some of which have been noted in a recent number of this paper, the records of the Patent Office appear to be singularly devoid of such devices.

Among the few patents relating to this subject is that to Chaubassargues, granted in France, which shows (see Fig. 12), a device for indicating ascent or descent, comprising a vertical tube 1, having flaring open ends, a paddle wheel 2, projecting into the tube, and an indicator wheel 3, having graduations upon its periphery and driven by the paddle wheel. When the machine is ascending the air enters the tube at the top, rotating the wheel 3 clockwise and moving the indicator wheel to indicate upward travel, while in descending, the reverse takes place.

A second device for the same purpose but of different construction is shown in another French patent, that to Brisson, wherein a series of balls are allowed to fall upon a resilient support carrying an arm provided with a pencil, which last rests upon a constantly rotating, paper-covered drum. It is stated that so long as the machine remains at a given level, the trace of the pencil upon the drum, caused by the impacts of the falling balls will lie in a straight line, but if the machine commences to rise the falling balls will strike the support sooner than when the machine is stationary, thus causing the pencil trace on the drum to vary from the normal straight line, the new pencil trace being above the normal, while if the machine should descend, the reverse operation will take place.

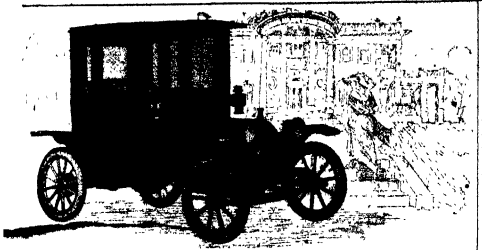
Along somewhat the same line may be noted the device patented to Pennington in Great Britian in 1908, wherein a mercury barometer controls, through an electrical circuit, the direction of thrust of a screw propeller, and by this means serves to keep the machine at the same level, and

Let's Stop Wasteful Deliveries

PERHAPS you think your delivery isn't wasteful. Unless you use motor trucks all the facts and figures are against you. By motor truck we mean a real truck—one designed and built to endure—one with a requisite strength in every part to last.

The heat killed twelve thousand horses in two weeks of July in New York City alone, and no one knows how many horses are permanently maimed, spavined or shot because of broken legs on account of the slippery, icy pavements each winter. The finer your equipment of horses and wagons the bigger the toll you pay in bad weather, whether it is from heat or ice; and these are but a few of the drawbacks to a system which the motor truck is rapidly making obsolete.

Let's Try White-Truck Economy



THE economy of the good motor truck is found in its greater capacity—its better speed—its ability to keep agoing. A motor truck is no more tired on the last trip than on the first—it is just as efficient. In any other department of your business you know what efficiency means, but in your delivery plant, that vital link between your factory or your business and the customer, you have not demanded efficiency. White motor trucks will make it efficient. We know it, because they are doing it—not for a few firms—but for scores in every kind of business under every possible condition—for the largest, shrewdest and most capable firms in the country. They are not deceived—you simply have not been shown.

The White line has every size you want—1500-lb. delivery wagons, 1½-ton, 3-ton and 5-ton trucks—all with a standard type of engine, thereby reducing the mechanical problem to its lowest terms. The engine is so simple that any teamster can drive it and, knowing how to drive one White engine, he knows how to drive all White engines.

Let us give you some facts and figures about modern delivery plants—a catalogue, too, for the asking.

The White Company

838 East 79th Street, Cleveland

Three-passenger Coupe $1100. F. O. B. Detroit

Equipped with electric headlights, combination side and tail lights, three-light dome, electric dashlights in front. 32x3 1/2 inch rear tires, spare and tools. Interchangeable two-seat body with Coupe, only $40 extra

Consider the luxury of this $1100 enclosed

Hupmobile

More Hupmobile Coupes were sold last year than any other enclosed car of its type

The reason is obvious.

The Hupmobile Coupe ceased to be an interesting experiment and became a pleasant certainty two seasons ago

Consider the coziness and comfort of this enclosed car on sharp, chilly mornings, to and from the office; and back again to the house on wet or wintry evenings.

Consider its convenience for about-town business trips — for the journeys to and from the depot, for shopping purposes; for the theatre trips and afternoon calls

There is not a member of the family from the baby upward, that does not partake of its luxury

And all this at such blessedly small expense

There is no doubt at all but that the limousine is the height of motor car luxury — and the Hupmobile Coupe attains limousine luxury at an infinitely lower cost of upkeep

Your first investment in the Hupmobile Coupe is less than the annual deterioration of the costlier limousine — or any large and high-priced car

Ten dollars a month ought to cover your cost of operation of your Hupmobile Coupe — according to the experience of scores of owners.

Ask your Hupmobile dealer to take you for a spin some day in Autumn or early Winter, when conditions overhead and underfoot are unpleasant — and see how completely you escape the discomforts of those who go on foot or by trolley or in an open motor car.

Then figure how little this really great convenience and comfort cost you — and act accordingly

If you wish, your Hupmobile can be convertible into a Hupmobile Runabout for $50

HUPP MOTOR CAR COMPANY, 1233 Jefferson Avenue, Detroit, Michigan

Save Winter Storage on Your Car

ORDER NOW a

Pruden System Fire-proof Garage

Use next winter's storage bills to *pay half* the cost of a **Pruden Garage** and have your car always handy and safe. Many owners use their autos all winter long, keeping them in a **Pruden,** without heat.

Unit-Built Portable Handsome Durable as Masonry Low Cost

Pruden System Construction is entirely original with us and utterly unlike anything else. It gives you *fire-proof* protection in a building as handsome and substantial as masonry, at *one-third the cost.*

Here's the only portable garage that is wholly fire-proof. No wood in a **Pruden.** Entirely built of handsomely embossed *galvanized steel units* You erect it in a few hours with screw driver and wrench, and as easily take it down. **Pruden** buildings *last a lifetime,* never need repairs, do not depreciate in value and are *rigidly guaranteed.* You simply can't realize how different and how perfect the **Pruden** is in every detail until you get all the facts.

the somewhat similar mechanism patented by M. Phillippeau in France. This embodies a suitable case containing a spring-driven winding drum upon which the valve cord of the balloon wound, the rotation of the drum being normally prevented by a friction brake Mounted also within the case is an aneroid barometer, the indicator arm of which serves to make and break an electric circuit in which is included a magnet, the armature of which forms the aforesaid brake for the spring drum. When the balloon reaches a predetermined height, the barometer arm closes and completes the circuit thus withdrawing the brake from the drum and allowing the latter to revolve, thus opening the valve and permitting the gas to escape. The purpose of this device is to prevent accident due to the failure, or inability of the aviator to open the valve at the proper time

The self-registering aneroid barometer, in its ordinary form, appears to be capable of registering the ultimate height attained, provided this height is maintained for an appreciable time, and so far as the writer has been able to ascertain, none of these devices having any special modifications of structure for aeronautical use has been made the subject of a patent. It would appear, however, that devices of this character might be devised especially for aeronautical use, embodying great rapidity and sensitiveness of operation, together with freedom from the effects of motor vibration, and at the same time having indicators and scales of such size as to be readily discernable from the operator's seat, and doubtless as the art becomes more highly developed the demand for such instruments will be fully met by the active mind of the inventor.

An Inventor as a Congressman

IT is of considerable interest to inventors to know that the House Committee on Patents includes in its membership a man of such experience in patent matters, as an inventor and patent lawyer, as William H. Wilder, in view of the flood of bills that are being presented to the Committee with all kinds of changes proposed to our present patent system.

Mr. Wilder was born May 14th, 1855, in Belfast, Me. His inventive ability was probably derived from his father and grandfather, who were mill men, his mother being a school teacher. At eleven years of age he removed to Massachusetts, worked on a farm; went to school in the winter, and was, in turn, a wood chopper, worked in a card mill, prepared chair stock for the chair factories of Gardner, and when but a little over sixteen, went into business for himself as a painter, and has been an employer ever since. While in the painting business he climbed most of the meeting-house spires in and around Gardner. He entered the oil stove business in a small way, and in the first years of his experience he made the patterns and all the other parts, and directed personally the making of tools and dies and the like, for a period of twenty years. He has taken out more than fifty patents covering his own inventions.

Mr. Wilder is a member of the Bar of the Supreme Court of the United States. His inventions have revolutionized the oil stove industry; for he is the inventor of the modern oil stove. He has taken great interest in denatured alcohol, having visited Germany to investigate this business.

During a period of thirty-eight years as an employer of labor he has never had a strike, lockout, or disagreement with his employees.

Notes for Inventors

A Folding Step for Street Cars.—The Public Service Commission for the district in which New York is included, has been considering the betterment of the equipment of surface cars. The Metropolitan system is now experimenting with a folding step for the *pay-as-you-enter* type of cars. The present step is too high, and there have been some accidents.

United Shoe Machinery Patents.—How huge is the part played by patents in the profitable industry of

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best means of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us to many times to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

Branch Office, 625 F Street, Washington, D. C.

PATENTS SECURED OR FEE RETURNED
Free report as to Patentability. Illustrated Guide Book, and What to Invent with List of Inventions Wanted and Prizes offered for inventions sent free. VICTOR J. EVANS & CO., Washington, D.C.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

FOR SALE.

FOR SALE—Twenty acres of A deposit of very fine fire clay on the line of the Erie Railroad. For further information and terms apply to Wyatt & Company, New Durham, Alabama.

FOR SALE—A Patent Curtain Roller or Holder where a no pins, hooks or tacks are required. Full particulars and terms on request. A. Fahrenwald, Fall River, Thompson Block, Providence, Rhode Island.

CLEARANCE SALE—Engineering Instruments, Manometers, Indicators, Planimeters, Gauges, Scales, Surveying Instruments, Slide Rules, Books, Catalogue free. Standard Typewriter Exchange, 38 Park Row, N. Y.

HELP WANTED.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man who can call upon retail trade after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to work a lucrative business. No position or soliciting. Unusual financial opportunity for a man in your position to get into a big paying business without investing capital. Address, Manager, 1947 Monadnock Block, Chicago.

POSITION WANTED.

SUPERINTENDENT AND MASON, connected with one firm 20 years, desires position with manufacturing company. Address: Engineer and Contractor, Box 54, New York.

WANTED.

WANTED—One first-class marine engine and boiler engineer, $4.00 per diem. A competitive examination will be held for the position December 15th. For further information address, Commandant, Navy Yard, Charleston, S. C.

MUNN & Co.—Desires to secure the services of a competent patent attorney, skilled in the preparation of patent specifications. Address Munn & Co., Patent Attorneys, 361 Broadway, New York City

MISCELLANEOUS.

FULLY QUALIFIED ENGLISH ENGINEER (A. M. I. C. E.), resident in London, already acting as representative for a few good firms, is prepared to undertake similar agency for one or two good products. Experienced also in negotiating the sale or license of British Patents for manufacture. Highest references. Address, Engineer, Box 773, New York.

THE LOGARITHMETIC TRIANGULAR RULER. Saves time in making mechanical drawings. Can be moved over work like T-square without injuring it. Send for circular. The Logarithmetic Instrument Co., Wilmington, Del.

IF YOUR PATENT is of value I can help you to get it on the market. For full particulars address R. Smith, 1819 Bridgeport Building, Chicago, Ill.

JUST INVENTED a bottle cap that cannot be pulled after corkscrew, useful for all liquids. Write for particulars. Corker, 1 Madison Avenue, West 23rd Street, New York City

MOTORCYCLES CHEAP.—Send to-day for free catalog of new and used motorcycles. Also motorcycle accessories and attachment motor parts for converting bicycles into motorcycles. Shaw Manufacturing Company, Dept. N, Galesburg, Kans.

GINSENG Raising is the surest way to make big money on little capital. One acre will yield $20,000. Seeds at $3 a lb. I will buy all you raise. Tells you where. Keep your secret only. If you are not satisfied with your present investment, write at once. Address, Wm. Hamilton, Box 1, Louisville, Ky.

KOSTER'S KOMBINATION KIT is handy to have and novel. Comprises six pair of jaws, separated by one pair handles. Proper combination for almost every mechanic and user's tools. Manufactured of tempered hardened, by our own expert workmen, from special crucible steel forms, exclusive territory. Write for catalogue. Corrugated Manufacturing Co., 65 Wright St., Carbondale, Pa.

MAKE BIG MONEY operating a Dardanelle Post Card Machine. Prints postal cards with your name and address the spot in two minutes in the finest style. Big daily profit guaranteed. Write for free booklet. Dardanelle Photographer to make first class photographs. Pays a good profit of $25 per week. Write to-day for free booklet and catalogue. Dardanelle Specialty Co., Dept. B-1, St. Louis.

FREE—"FORTUNE FOR PROFIT" Magazine, send us your name and 10 will mail you 5 copies absolutely free. Before you invest a dollar anywhere—get this magazine. It is to your interest to get it. We help intends to invest $5 or more in any enterprise. Write to-day. Fortune for Profit, 1 Madison Ave., New York City.

SENT DOUBLE POWER PLANT APPLIANCE. One of the five exclusive features of the Detroit Motor Boat also automatic, reliable and simple. Any inexperienced person can operate it. Starts motor, runs it, stops motor, and reverses it without touching any other controlling lubricating and electrical devices. Other pressing lubricating and electrical devices. Other pressing features. Write for catalog. Detroit Motor Boat Co., 36 W. 32nd St., Kansas City, Mo.

UNIVERSAL LATHE CHUCK. Self centering, self tightening, self releasing. Will hold any shape work for turning, etc., without wrenches. Send for circular. Universal Lathe Chuck Co., 1 Madison Ave., West 23rd Street, New York City.

WIRE SHORT WORDING. Send for free booklet. Shows how to write telegrams and cablegrams to save money. Western Electric Co., 114 Fifth Ave., Chicago.

this country has undergone in the last half century is shown by the proceedings of the United Shoe Machinery Company. This "trust" owns at least a thousand and possibly fifteen hundred United States patents. A mere list of them alone covers 48 pages of legal cap. In some instances many patents have been granted to one inventor. John B. Hadaway has received about 75 patents, and Thomas G. Plant also a large number. The "trust" also owns hundreds of foreign patents.

A New Hose-supporter Wanted.—A man of our acquaintance says he does not like a hose-supporter which encircles or grips his leg or one that is connected with and drags down on his undergarments, both such forms being on the market. Cannot someone invent a supporter that will hold the top of a sock up and avoid both of the above described objectionable features?

A Machine for Making Imitation Stitches.—John B. Hadaway of Brockton, Mass., assignor to United Shoe Machinery Company, has secured three patents, No. 1,003,450 to No. 1,003,452, for machines for making impression or imitation stitches. The patent, No. 1,003,450, has an indenting wheel which is rolled back and forth over the work and is also caused to feed the work during its rolling movement. The patents, Nos. 1,003,450 to 1,003,452, were issued September 19th, 1911, on applications filed, respectively, July 18th, 1904, September 15th, 1904, and March 22nd, 1905, so that the applications were pending in the Patent Office from six to seven years. This inventor, John B. Hadaway, is one of the most prolific inventors in the shoe machine art and was the patentee of a patent, No. 521,978, for a machine for the same general purpose as the three above specified. The patent, No. 521,978, was granted June 26th, 1894, and consequently expired last June. The application on which this expired patent issued was filed in the Patent Office March 28th, 1894, and as the patent issued June 26th, 1894, the application was pending less than three months, in striking contrast to the three patents just issued.

Protecting from Electrolysis.—Albert B. Herrick, in a patent, No. 1,003,604, describes a method of preventing an earth conductor adjacent a grounded return by alternately connecting the earth conductor to the grounded return and to a source of negative electromotive force.

Sterilizing Earth Around Posts.—Patent post holes have long been humorously referred to in connection with machines for grinding smoke, left-hand wheel barrows, and other imaginary inventions. It has remained, however, for a Budapest inventor to make what is probably an important improvement relating particularly to post holes, seeking to thus preserve the wood of the posts. Instead of applying preservatives to the wooden posts, railroad ties, sleepers or other wood exposed to the action of the earth, he treats the earth which surrounds the wooden post in such manner as to destroy all insect, germ and fungus life by soaking the earth with a suitable sterilizing liquid. The process is termed "Feristerilization," and is claimed to be especially useful in rural and other remote districts in which it is inconvenient to obtain wood which has been treated with creosote or similar preservative.

Cork Plugs for a Novel Purpose.—Cork plugs are utilized in a cotton gin roller, patent No. 1,002,842, to William H. Harries of Pawtucket, R. I., assignor to Empire Duplex Gin Company of New York city. The roller has a number of radial recesses, and the plugs of cork are fixed in the recesses and project beyond the surface of the roller. The cork plugs are described in the patent as constituting the operating cylinder surfaces of the roller, and the specification is interpreted by manufacturers and in otherwise advantageous, since the cork plugs being fixed in the recesses, may be readily removed when worn or damaged.

Reward of New York City.—Mr. Churchward, assignor to General Electric Company. To assuring the desired result, Mr. Churchward provides the motor with a series and a shunt field winding, and means for connecting the motor as a series motor for running and for connecting the shunt field winding in circuit and for reversing and shunting the series field winding when the motor is regenerating.

A Coaster Bar for Roller Skaters.—What is termed a roller-pole toy has been patented, No. 1,003,537, to Thomas S. Spivey of Cincinnati, Ohio. It consists of a pole, having a roller at one end and a handle at the other end, the rider sitting astride the pole on a seat. In front of the rider there is provided on the pole a cross bar between the seat and the handle, the knees of the rider bearing below the brace bar, so that when the rider is sitting, much of the weight is taken off the handle.

A Fireworks Auxiliary.—In patent, No. 1,003,411, to Haden Herbert Bales of Ashcroft, British Columbia, we find an airship frame with a battery of pyrotechnical rocket cylinders, adapted to operate as an auxiliary to the main propelling mechanism. Means are provided for adjusting the position of the rockets to regulate the direction of the discharge, and also a selective mechanism for firing any particular one or all of the rockets, as occasion may require.

An Illusion Apparatus.—A patent, No. 1,003,905, with Roy McHill of Somerville, Mass., as inventor, is for an apparatus for producing an illusory effect, in which a vessel is supplied with water from a pipe discharging from above and an exhaust pipe leads upward from the vessel into the first pipe so it is hidden by the water discharged into the vessel, a pump, out of sight, being suitably connected with both pipes to properly circulate the water

Three Patents to Charles Francis Jenkins.—Charles Francis Jenkins of Washington, D. C., has secured patents, No. 1,003,750, for a gas engine starter; No. 1,003,751, for a railway tie of metal and concrete with a special rail gripping device, and No. 1,003,752, for a gas motor starter.

Legal Notes

A Void Patent.—The Regnier patents, No. 678,514, for a vegetable or fruit slicer and method of making the same, and No. 744,107, for a slicer to produce such slices, *Held* void for prior public use. Handy Things Company v. Tucker & Dorsey Manufacturing Company (C. C. A.), 188 Fed. Rep. 68.

Substantive Patent Law and Procedure.—In a hearing last year before the Patent Committee of the House of Representatives, one of the most distinguished patent lawyers of the country said, in commenting on the substance of the patent law and the practice thereunder, as follows:

"The patent law, the substance of the law, in this country I think is admirable. I do not think there is any branch of law where the substance is in better shape than in the patent law to-day. When you come to procedure, that is, the way in which cases are tried, nothing could be worse."

Warning to American Trade-mark Proprietors.—In a note, published by the Bureau of Manufactures, American Minister John B. Jackson, Habana, Cuba, gives a warning and extends some good advice to owners of trade-marks, as follows:

"Under the provisions of the existing Cuban law with respect to trade-marks any person whatsoever can legally register well-known foreign trade-marks and deprive the foreign owners of such trade devices of the benefits arising from their possession. This has happened recently in several instances involving patent or proprietary medicines. When the third party has once registered the trade-marks in due form under the law the only redress possible for the rightful owner or originator is to bring action for fraud, and proof of fraud is naturally very difficult under such conditions, even in the most obvious cases.

"The registration of trade-marks is a simple and inexpensive matter in Cuba, and rightful owners may easily prevent difficulty by having their trade-marks registered at once wherever there is any likelihood of entering the Cuban market. It is urged that American manufacturers take note of this matter and by forestalling the registration of their trade designations by pirates in the future avoid future annoyance."

$1800 Self-starting

Chalmers "Thirty-six" Leads

Our "Thirty-six" was the first medium-priced car to have these features

Self-starting device
Does away with cranking. Simple air pressure type. Nothing complicated—just press a button on the dash and away goes your motor.

Genuine long stroke motor—4¼" x 5½"
Means better pulling, longer service, greater quietness, freedom from vibration.

Five speed transmission—four forward speeds and one reverse
Gives utmost flexibility of control and enables you to climb the steepest grades with speed.

Dash adjustment for the carburetor
You can get the proper mixture to suit the varying weather conditions without getting out of car and lifting the hood

36" x 4" tires and Continental Demountable rims
These big tires do away with tire trouble and insure ease of riding. Demountable rims rob punctures of their terrors.

Genuine honey-comb radiator, cellular type
Same radiator found on highest priced cars Means perfect cooling, longer life, good looks.

Bosch dual ignition
Simplest system yet devised. Nothing equals a magneto for furnishing perfect ignition.

(Read that over again It is hard to realize at one reading that all these big features are really present in one car selling for $1800)

The famous Chalmers "36" is continued for 1912, representing even greater value than ever before The price, $1500, includes magneto, gas and oil lamps, Prest-O-Lite tank, top and windshield The Chalmers "Forty" at $2750 is continued for those wishing a 7-passenger car. See these cars at our dealers. Catalog on request

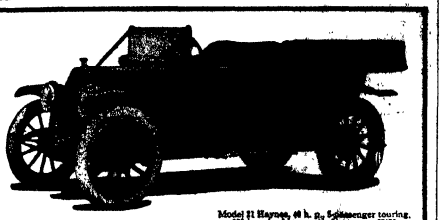
Chalmers Motor Company, Detroit, Mich.

"Mack"

Leading Gasoline Truck of America

"Mack" Superiority

IF it were possible for us to take every prospective truck buyer through our immense plant at Allentown, and show him how conscientiously and substantially "Mack" trucks are built; have him see every process, from the selection of the raw materials to the final coat of paint to the finished product, and last but not least, to see for himself the rigid "third degree" test over hill and valley which every "Mack" truck must undergo, before delivery to the buyer, then he would realize—as thousands of representative business firms do—that the "Mack" is truly



The Leading Gasoline Truck of America

The ease and economy of operation, the power to extend your commercial area, the manner in which a "Mack" outstrips competition is left to be told in a highly illustrated catalogue which will be cheerfully mailed upon request

Model 21 Haynes, 48 h. p., 5-passenger touring. 120 in. wheel base. 42x6 tires. Motor. $2,100.

The Haynes for 1912 has received a royal welcome

IF ANY further evidence of the place which the Haynes car holds in the minds of the discriminating public were needed, it was furnished by the overwhelming response to our announcement of the 1912 Haynes.

By reason of the fire which completely destroyed our old factory last February, the Haynes car virtually had been out of the market for seven months. During those same months, other manufacturers were going to the public day after day, month in and month out, with their advertising, with their salesmen, and with their announcements of new models while *we* were at a standstill.

Last month, when our magnificent new factory had risen from the ashes of our old one, when its wonderful modern equipment had been installed and our first 1912 model had been built and tested and *proven* to be the best of all the splendid Haynes models ever built, *then* we came back into the market. It was a glorious return and the welcome has been beyond all expectation. We hadn't realized it but the public was *waiting* for the new *Haynes.*

The 1912 Haynes [illegible] classes, Model 21 and Model Y, 50-60 h. p., eight [illegible] superb, high-power car, and built [illegible] skill. Model [illegible] Haynes dealer now, or

Hy-Rib is a Money Saver

Concrete costs are greatly reduced by using Hy-Rib Steel sheathing because it does away with centering, wood forms, and special equipment. Merely set up the Hy-Rib, apply the cement and the work is complete. A strong, permanent, fireproof construction—more economical than wood, stone or brick.

Hy-Rib for all Buildings

In Walls and Siding, Hy-Rib makes a thin, monolithic wall at half the cost of brick. In Roofs, Hy-Rib reduces the dead weight and does away with centering. In Partitions, Hy-Rib saves all dead weight, and lowers cost of labor. In Ceilings, Partings, Joists, Silos, Culverts, etc., Hy-Rib is a money-saver.

If you write us about your needs, we will send you (1) Hy-Rib Handbook, full of details, data, figures, suggestions, and specifications; (2) Hy-Rib, and samples on the Farm—specimen sheets of tile, brick, linoleum, tobacco, leather, etc.

Whirling Rain Drops on the Car Window

To the Editor of SCIENTIFIC AMERICAN:

On a rainy day the observing traveler will doubtless be surprised to find that every rain drop on the car window by his side becomes a miniature whirling vortex as long as the car is in motion at speeds above ten or fifteen miles per hour. The effect is most easily noticed when the rain drops have collected enough fine particles of soot to make their motion apparent. While the largest drops show the greatest movement, the rotation can be detected even in droplets down to one-eighth inch in diameter

when the train is running at high speed. The direction of rotation for each individual drop is the same as that of the car-wheels, the cause of the motion doubtless being due to wind friction against the lower rounded side of the water drop. The pear-shape form of the drops, especially the larger ones, where the attraction of gravity for the mass gets the better of the surface tension, which tends to hold the spherical form, results in a greater rotational moment at the rounded bottom than at the thin, wedge-like top, so that the wind friction at this lower surface produces movement in the same direction as the car wheels below.

O. H. C.

Chicago, Ill.

Metric Wire Gage

To the Editor of SCIENTIFIC AMERICAN:

From a very reliable source I learn that the Committee on Weights and Measures of the next Congress will report a bill doing away with our old-fogy system of having different-size measures for different articles. For instance, we have a large quart for berries, beans, peas, etc., and a smaller quart for liquids. In the matter of weight we have avoirdupois, apothecary, and troy, no two of which are alike. Equally absurd as the above is the great number of non-standard wire gages, none of which has a base that is get-atable as a starting point, and no two that agree thereafter. To overcome this "conglomeration" in gages, the writer some time ago designed one (for both metal and wire), that is standard throughout. It takes for its base the same angle (of one degree) upon which the metric system of measurements is founded. It starts at the apex of this angle for its first number, and gives it as No. 0, which is really no

no substance, however small, can enter there. To locate No. 1, we measure along either side of the angle one millimeter; for No. 2, measure two millimeters from No. 1; for No. 3, go three millimeters from No. 2, and so on *ad infinitum*. It will be noticed that each gage number indicates the number of millimeters intervening between that number and the next smaller one below, and that every number is of good commercial size.

To illustrate its practicability, suppose a party in some isolated place had a piece of wire and wished to order more like it, but had no gage. All he would have to do would be to lay out an angle of one degree, insert his wire and measure the number of millimeters from its point of contact to the apex of the angle, then point off the gage numbers as above, and he has the exact size—a thing that cannot be done with any other gage made.

The accompanying drawing plainly shows for itself. The engraved angle in the center is exaggerated for purposes of illustration, but it represents an angle of one degree, on one arm of which are millimeters, and on the other the gage numbers, engraved simply to show the principle of the system, while on its outer margin are the usual slots cut out for the different sizes, with the gage numbers at each separate slot, all of which is as simple as "rolling off a log."

MERRITT W. GAUSWOLD.

Highwood, N. J.

Twenty-seven-knot Armored Cruisers Urgently Needed for the United States Navy

To the Editor of SCIENTIFIC AMERICAN:

Having just read in your issue of July 22nd your most interesting comparison of the United States and German navies, I would like to have your explanation of the policy of the United States navy, which omits the dreadnought armored cruiser type as found in the British and German navies, and of which type Japan is now said to be building more than the battleship type.

With even one ship of the British "Lion" type, an admiral in charge of our ten dreadnoughts of the "Texas," "Wyoming," "Utah," "Delaware," and "Michigan" classes, could send his one 30-knot dreadnought to locate the enemy. Our light 24 to 26-knot scouts of the "Chester" class, and our 23-knot armored cruisers of the "Washington" classes, would obviously be completely at the mercy of British, German, or Japanese dreadnought cruisers of 28 to 30 knots speed, and it would be murder to send our good fighting men out in such ships.

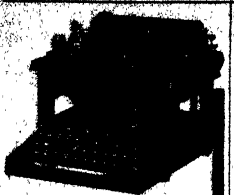
Would not these navies possess a great advantage on this account?

How could our admiral "find the enemy," and destroy him when the enemy, by means of their dreadnought cruisers, would be able to keep in touch with the movements of our fleet, while our admiral would be in the dark?

Ought not our next two ships to be of the "Lion" type, or at least one of them?

A. B. IRVINE.

St. Marc, Haiti.



[Our correspondent has placed his hand on a weak spot in the make-up of our fleet. For some years to come our annual naval programme should call for two battleships and two armored cruisers of the "Von der Tann" type. Our "Chesters" (25 knots) and "Washingtons" (21 knots) would be helpless in the presence of the 26 to 28-knot 12-inch gun armored cruisers of foreign navies. —Ed.]

Foreign-built Dredgers Built to the Order of the United States

To the Editor of SCIENTIFIC AMERICAN:

There is announcement made that a Glasgow firm has just launched the United States dredger "Norfolk," built to the order of the United States [illegible] mint.

The order was placed [illegible] and [illegible]

Building Character in a Writing Machine

L. C. Smith & Bros. Typewriter

(BALL-BEARING, LONG-WEARING)

Every part of this typewriter is made as if it were the one product on which the factory's reputation must finally depend.

Every part is designed to produce, by itself and in conjunction with every other part (not only for the expert typist under favorable conditions, but for the ordinary operator under all sorts of conditions), the perfect work by which the L. C. Smith & Bros. Typewriter must be judged.

Character is built into the L. C. Smith & Bros. Typewriter. It makes this typewriter the always dependable writing machine you want in your office.

Speedometers, Odometers, Tachometers, Counters and Fine Castings.
Represented in United States by Manby & Co., Limited, 7 City Road, Finsbury Square, London, E. C.; France, by Manby & Co., Limited, 107 Avenue Parmentier, Paris, Germany, Austria-Hungary and Scandinavian Countries by Lucas, Limited, 8 Ch., Hatton Street, Hatton Garden, London, E. C.

can builder made tender, and it was so much higher than the foreign builders offered to build for, that President Taft felt justified in vetoing the resolution of Congress prohibiting work for the United States to be done in foreign yards. The difference between the foreign bid and the one bid tendered by the American company that bid, amounted to almost $100,000

In other cases the government exercises its power and avails of foreign tonnage, rather than pay the American "scale" of freight charges. Annually several thousand tons of coal for the account of the government are transported from Virginia to San Francisco and Portland, Ore., foreign tonnage can be had to move it for sixty per cent of what the American-built tonnage charge. The government contracts with the foreign tonnage, and the coal is moved on the low rate.

If an American company has coal to move from an Atlantic American port to an American Pacific port, it is compelled to use American tonnage and to pay the American freight scale

The government of the United States refuses to obey its own laws. The United States government shows that the navigation laws tend to extortion The United States government compels the people of the United States to obey the navigation laws and to pay extortionate freight rates.

Is it not time to consider the revision of these navigation laws, that have been in effect for over one hundred years, and which have practically driven us out of the foreign shipping trade and been the means of extortion and monopoly in the domestic? If the government of the United States refuses to obey its navigation laws, why should the citizens of the United States be compelled to?

There is a remedy for this state of things; allow American registration for foreign-built American-owned tonnage, limited if necessary to foreign trade, and put all iron and steel and shipbuilding material on the free list We will then be able to compete in building with foreign yards.

As long as iron and steel are highly protected, and as long as iron and steel made in this country is sold from $8 to $11 per ton cheaper to foreigners than to our home builders, we will be unable to meet the competition of foreign builders of tonnage.

There is depression in United States trade. Many of our yards are on short time We want a revival of our American merchant marine The surest way to bring it about is to reform the navigation laws, and allow Americans the privilege of "free ships" the same as Great Britain and Germany allow to their people.

Also we should break the monopoly that exists in the iron and steel trades by taking off all duties.

Chicago, Ill. CHARLES DEPESSE.

General Factory and Machine Shop Lubrication

IT is a matter of common knowledge among well informed factory managers that the power loss due to the friction developed in the moving parts of machinery, is considerable. In the endeavor to reduce this absorption of power experiments have been and are being made with types of roller and ball bearings Lubrication, however, is a question just as important. As a consequence of the failure to appreciate the necessity for the investigation of lubricating problems and choice of lubricants, the possible saving in this direction is frequently very large.

A considerable reduction in power can usually be effected by simply changing the oil. These reductions will in many cases be approximately the same as the substitution of roller or ball bearings for the ordinary type of bearing. This being the case, it seems advisable to consider the elements bearing upon efficient lubrication in a practical way and the necessities for the right quality of oil in the right place.

When reductions in power to the extent of ten or fifteen per cent in the driving of workshop machinery and shafting are easily brought about by the re-establishment of oils or the use of more suitable lubricants, and when this reduction of power can in many cases be brought to

The Warner Is the Official Road Map Speed Indicator

THE WARNER was used in compiling the routes in the Automobile Blue Book, King's Official Road Guide and the dozens of Official Guides put out by Automobile Clubs and map makers.

Note how this affects *you*—

You tour unknown territory occasionally. You must depend on some reliable map or ask your way at frequent intervals with unsatisfactory results. Some people delight in directing Automobilists to take the worst roads or the wrong road.

With the Warner Auto-Meter on your car the road map directions are easy to follow. It is impossible to go wrong. Where the route book says: "21.6 miles—four corners. Turn right at country schoolhouse; bridge over creek ¼ mile away"—you will find the four corners and the schoolhouse just when the route book says—at 21.6 miles, no more and no less.

Note this little human interest story which bears on this point.

Early in June a car drove up to our Beloit factory. It bore an Ohio license number. The owner was driving. With him were his wife and two daughters. One of the first things he said, after introductions and greetings were over, was: "I had only had my car a week when we decided to drive from Columbus to Madison, my old home, in the auto. And do you know we *haven't yet asked a direction from a single human being*, relying entirely on our route book." The directions came out right because the routes were surveyed—and interpreted—by Warner Auto-Meter.

This case is only one of many which have come to our notice.

There are conditions when touring becomes a nightmare instead of a pleasure.

The different route book and map makers have themselves advertised the fact that the Warner was adopted by them as their "Official Speed Indicator," because after testing all makes they found the Warner in every sense the sensitive, accurate, dependable and reliable instrument of precision we have claimed it to be.

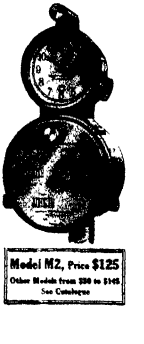
When an *inaccurate* and unreliable speed indicator is used to interpret an *accurately surveyed* map or route, disaster results.

In such cases where the route book says: "49.8—forks in road with big elm in angle. Take the left branch" You are likely to find nothing in sight but open prairie or you may be approaching a four corners or small town So you are *lost* unless you stop to ask questions, and this is what a route book is intended to prevent.

The route book maker's principal tribulation is explaining to owners of unreliable speed indicators that their routes, compiled at a cost of thousands of dollars, are *right* and that no one using a Warner speed indicator to interpret them has cause to complain.

A little Warner device which adds still further to the joys of Touring.

All Warner instruments of the dial type (see illustration) have two resetting buttons for the trip mileage figures. One resets the figures to 000.0 with a single turn. The other works on the tenths of a mile only, making it possible to turn up any desired mileage on the trip scale This makes it possible to drive around the boulevards or through the parks at any point and then in a few seconds set the mileage back to correspond with the route book readings Those who tour regularly will appreciate this refinement



The Warner costs more than inferior speed indicators for a very good reason.

Those who look for satisfaction on the bargain counter are certain to be disappointed We have all had our lesson. Supreme quality is worth its cost And—as in other things—the Warner is also the *cheapest* speed indicator obtainable if you base its price on *years of service* or *miles of travel*. It is a permanent investment because it remains as sensitive, accurate and reliable as when new for many years—or many hundred thousand miles.

WARNER AUTO-METER

"The Aristocrat of Speed Indicators"

THE Warner can be secured through reputable Automobile Dealers in any city or town in the United States. Warner branches are maintained in all the principal cities for the convenience of these dealers and their customers. Inquiry to Beloit or at our branches is invited for Warner literature.

Good-Bye, Corns No Wait–No Pain

Just listen to this. There is a little plaster which holds a bit of soft wax—a wondrous invention called B & B wax. This little plaster is applied in a jiffy, and the pain of the corn stops instantly.

But that isn't all. That bit of soft B & B wax gently loosens the corn. In two days the corn comes out. No pain, no soreness, no inconvenience—no feeling whatever. The callous simply separates itself from the toe, and the trouble ends.

Five million corns annually are removed in this way—removed by Blue-jay plasters. Get a package—end yours, too. Don't temporize with corns.

A in the picture is the soft B & B wax. It loosens the corn.
B protects the corn, stopping the pain at once.
C wraps around the toe. It is narrowed to be comfortable.
D is rubber adhesive to fasten the plaster on.

Blue-jay Corn Plasters 15c and 25c per package

(B) Also Blue-jay Bunion Plasters. All Druggists Sell and Guarantee Them. Sample mailed free.

Bauer & Black, Chicago and New York, Makers of Surgical Dressings, etc.

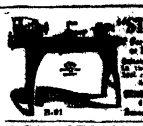
as high as thirty or forty per cent, it is very evident that the investigation of this subject is worth considerable time and trouble.

Because a good quality of oil is bought by the purchasing agent of a company it is not always true that this oil is used to the best advantage in the works. As an example: If an oil similar to a high class dynamo oil is bought by the purchasing agent in large quantities for a general machine shop and, as frequently happens, a considerable portion of this oil be mixed with either cylinder or black oil—to suit the operator's idea of what he imagines is the proper compound for general lubrication of machinery—the mixture is not at all adapted to the work which it is made to perform; and (if the original oil is being mixed with cylinder oil, as is sometimes the case) the cost is greatly in excess of what it should be, and the efficiency of the oil as a general lubricant is considerably impaired, even though the cost has been increased.

It is impossible here to make any statement as to the use of different classes of lubricants for certain purposes, as the conditions of speed, pressure, class and arrangement of machinery, the devices employed for the lubricating, etc., have considerable effect, not only upon the oil which can be used but upon the character of oil which is most efficient for the work.

It may be stated, however, that the use of light oils is possible only where special mechanical devices are arranged for the purpose of lubrication or where the shafting has the proper ring oiling bearings, etc. It is also true, as a rule, that floor machinery cannot be lubricated satisfactorily with the same oil that is used for modern shafting. Floor machinery itself can very well be divided into three classes, each class being lubricated with a different oil.

In the lubricating of plants of a general character it is customary to use grease or solid lubricants for some purposes. In some cases greases can be used with economy, but an excess of grease will act against the actual economy of operation on account of the increase in power required to overcome friction of the parts where the grease is used. It is invariably the case that grease will require the development of more power than necessary where oil is being used, and the only features that commend grease as a lubricant are its greater cleanliness and the fact that less attention is required in the lubrication of the various units.



Where bearings have some mechanical fault of construction or alignment, or are roughly fitted, or where it is not worth while to produce a proper fit, they absolutely require grease as a lubricant; but even under these conditions such bearings can be lubricated in some cases more cheaply by the application of heavy cylinder oil.

In considering the efficiency of lubricants for general purposes, the fact that grease will reduce the bearing temperature of an improperly constructed or mechanically imperfect bearing should not be taken as indication that the same results will obtain from the use of grease through the entire plant, where probably almost every other bearing is in good condition.

It is very frequently the case, however, that grease is placed in a shop for general lubrication on account of just such a misconception from its work upon an imperfect bearing, the imperfections in the bearing not being taken into consideration. The fact of the matter is that the reduction of the temperature in this case which follows the use of grease in the bearing is the result of a special condition and does not illustrate the general applicability of the material.

The amount of oil required to provide proper lubrication in order to reduce the friction loss as nearly as possible to a minimum is so small that if it were possible thus to reduce the amount used the oil accounts of every company would be cut in half and in a number of cases possibly a large reduction would be undertaken.

The high oil accounts as a rule are due to the waste of oil. In order to reduce this waste and bring it down to a proper proportion of the amount of oil necessary for the lubrication of the machinery, etc., it is absolutely necessary that appliances should be installed which will enable the

proper care to be exercised in the use of lubricants.

The installation of the gravity feed system, of appliances for catching the waste oil as it comes from the bearings, etc., so that this oil can be cleaned and re-used, the use of ring oiling bearings pad lubricators, sight feed pressure pumps and pressure lubricators are all necessary for the elimination of the waste of oil and the consequent reduction in the amount paid out on account of lubrication.

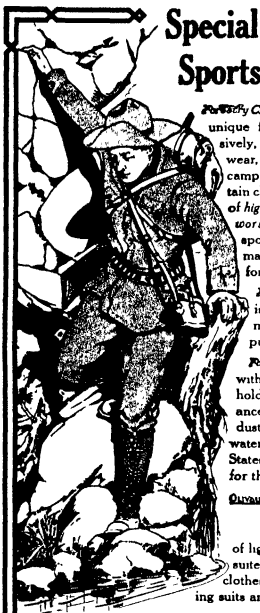
If the gravity feed system be employed, the oil can be used indefinitely, and, besides the economy secured from the re-use of the oil, additional power economy is obtained from the fact that a large amount of oil can be used by flooding the bearing and consequently securing a good free film of oil between the surfaces which assist in the efficient lubrication and reduction of temperatures.

All devices which are installed for the purpose of saving otherwise waste oil require that the oil used for lubrication shall be excellent in quality. A poor quality of oil will not stand continuous use without entirely breaking down and consequently defeating the very purpose for which it is to be used—that is, the reduction of loss by friction.

A great many shops, while they are heated during the working hours in winter, are apt to become cold during the night, and in order to provide efficient lubrication under these conditions the oil should be of such a character that it will remain fluid during cold temperatures. Under these conditions it is necessary that the oil shall have a (low) cold test, of at least 25 degrees above zero, in order that the lubrication be effective.

The science of lubrication is a very intricate one and the problems to be handled are so many and involving as they do the mechanical conditions of the plant, the physical and chemical characteristics of the oil and the partly physical and partly chemical action arising from the conditions under which they work, that it is impossible to do more than state these one or two general points in an article of this kind. In fact it is necessary for effective lubrication that this matter should be handled by a man who is expert in both the theory and practice of the science, otherwise even the most effective devices employed for the purpose of saving the waste oil and allowing efficient lubrication will be of little avail in the actual reduction of lost power by friction.

Practically the only people who have had a large and varied experience in the science of lubrication are the experts employed by the large oil manufacturing companies who have had the opportunity of gathering data regarding the conditions presented in practically all the variations possible, and are therefore constantly accumulating information showing that the systematic and careful study of lubrication has resulted in a reduction of the lost power and consequent expense in the operation of machinery, and in further reductions in the amount of oil used; to the benefit of users of power of all kinds; and in addition to this fact such a study has resulted in the production of oils better suited for the purpose of lubrication from a manufacturer's standpoint so that the continual tendency is to provide possibilities of further reduction of the loss due to friction in moving parts of the machinery and other apparatus



The Business Side of Aviation

(Concluded from page 837.)

a novelty and are rapidly becoming a necessity. Even special clothing for aviators is now being made, leather being a favorite material Numerous kinds of map cases, portable buffets, helmets, searchlights, and horns are offered specially for aeroplaning.

There is also much done in France in the manufacture of instruments for aeronautical work, speedometers, recording barographs, altiscopes, sketching cases and specially mounted compasses.

Coincident with the large trade in aeroplane supplies and in aeroplanes themselves, there has arisen a large number of firms in France, acting as aeroplane brokers, receiving orders and transmitting them to the manufacturers. Dealers in second-hand machines and supplies are also springing up, but their field is

Special Fabrics for Sportsmen's Apparel

Forestry Cloth (Shade No. 65) is a unique fabric, made by us exclusively, for men's and women's wear, for such special uses as camping, fishing, golfing, mountain climbing clothing It is made of *highest grade, strictly pure, all wool worsted*—which experienced sportsmen know is the only material entirely satisfactory for outdoor garments

Forestry Cloth (Shade No. 65) is a beautiful Olive Green, a more perfect shade for the purpose could not be found

Forestry Cloth (Shade No. 65) withstands the roughest use, holding its shape and appearance under all conditions. It is dust and wind proof, and sheds water. Adopted by the United States Government as standard for the Forestry Department.

Olivanto Cloth (a fabric similar to the above in weave) is made in an attractive shade of light brown, and is especially suited for riding and driving clothes, motorists' apparel, outing suits and raincoats.

Samples of *Forestry Cloth* and *Olivanto Cloth* sent upon request. And if you are unable to procure these fabrics from your tailor, we will see that you are supplied upon receipt of price. When ordering specify fabric and number of yards desired. *Forestry Cloth* $2.75, *Olivanto Cloth* $3.50 per yard.

American Woolen Company's Blankets

For Camp, Bungalow and General Outing purposes, meet every requirement for warmth, comfort and wear. Priced from $3.50 to $10.00 according to weight, design and quality. If your dealer does not carry them, write us and we will tell you who does or see that you are supplied

Oswego Serge is a staple year-round fabric for men's wear, a Serge-at-its-best, which—owing to its dependability—has been produced year after year in increasing quantity by the

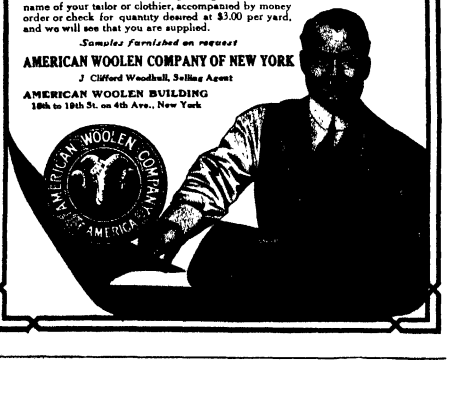
American Woolen Company

Wm M Wood, President.

Oswego Serge grows in popular favor, possessing those characteristics which appeal to well dressed men, and stamp serge as the fabric of universal wear.

You seek style, fit and finish. Let us speak for **Oswego Serge**—a masterpiece of the loom, possessing wear, feel, hang and finish Made of finest wool, and—quality considered—priced low

In order to be sure of the cloth when ordering a custom suit from your tailor, or a ready-to-wear suit from your clothier, insist on **Oswego Serge.**



If unable to obtain **Oswego Serge,** send us the name of your tailor or clothier, accompanied by money order or check for quantity desired at $3.00 per yard, and we will see that you are supplied.

still very limited—a second-hand aeroplane is a dangerous investment at best.

Even the profession of the law is called into the aeroplane field to a great extent the number of flourishing patent attorneys giving an indication of the amazing number of patents applied for.

The model aeroplane also plays its part in the industry and many model manufacturers sell several hundred of these toys at prices ranging from $1.50 to $20 Gliders, motorless aeroplanes, are also manufactured and sold, especially in England, where "gliding" is becoming a hobby

The number of corporations applying for certificates in various States, although only a few survive, gives a further indication of how active the field of aviation is becoming from the business side.

The Art.

It is not only in the trade and manufacturing of aeroplanes that a large volume of business is found Activity of another kind, but of equally great importance exists in the cultivation and practice of the art of flying.

A large number of men are employed by private individuals to fly their machines for them, and many manufacturers have a regular staff of expert birdmen to test, exhibit and instruct others on their machines

Few persons appreciate the actual cost of flying and what it means to keep as delicate a machine as an aeroplane in perfect order Atwood in his great St. Louis-New York trip, is said to have made over $6,000 in prize money It is understood on good authority that this falled by a large margin to pay his expenses

To keep an aeroplane in perfect trim two or three trained mechanics are required The wages of these men are $30 to $35 a week each, and often more

A Burgess-Wright aeroplane of the kind used by Atwood requires four gallons of gasoline an hour in flight, the gasoline costing about 20 cents a gallon, Oil, motor accessories, spare spark plugs, etc., also cost a considerable amount. The aeroplane, itself, practically used up in this grueling campaign, cost $5,000

In addition Atwood has large expenses for rents of fields and hangars, as well as damages to property, and in his own traveling expenses, his manager's salary, etc., are found other sources of expenditure The grand total amounts to well over $8,000—a rather expensive way to travel

At the recent aviation meets many of the contestants suffered heavy financial losses In most cases, however, the losses fall on the manufacturer who supplies the machine and who employs an expert to handle it.

The earnings of some of the aviators at the recent Boston meet are: Ovington, $11,782, Milling, $6,200, Sopwith, $6,022; Grahame-White, $5,224, etc., down to Ely, $150; and others with no winnings at all.

At Nassau, Sopwith won $4,850, while Atwood and Lieut Arnold won only a few hundred dollars.

There are other sources of revenue, however, in the actual flying of aeroplanes.

Passenger carrying at $25 to $50 a head is becoming customary in this country In England and France, regulation booking offices have been opened where reservation can be made The price is from $10 upward.

Manufacturers and aviators also make a considerable charge for instruction of pupils In France, $150 is the usual price for a full course. If breakages are to be included, the Voisin Company charges $500

At many aerodromes in England, where their location seems to be definite, hangars and the privileges of the field may be rented at $600 a year. The rent of the hangars in France is about the same.

The business of aviation is thus growing and the possibilities that are offered in the flying field for the development of industrial enterprises can probably be as little conceived of at present, as could the future of railroading one hundred years ago.

superstructure, the effect is that of a many-storied hotel. Ship beyond ship, over miles of water, stretches this floating city of twelve thousand souls. The thousands of incandescent lights become millions as they are reflected from the ever-restless water of the Chesapeake, emulating in numbers and beauty the flashing myriads in the over-arching dome of the autumnal night.

The "stern realities of war" seem very far removed, as I drink in the quiet beauty of the scene and catch the strains of well-remembered music faintly heard from a band on some distant ship The mood was deepened when a message came to the captain and the ward-room mess that night, inviting the officers to a moving-picture show—of all things in the world! But there it was; the screen hung between a 12-inch turret and the whaleboat davits; the machine at the taffrail; the crew crowded picturesquely on one side of the screen, the officers seated forward on the opposite side It was an audience that in size would have comfortably filled an average theater; for decorum it would have matched any house on Broadway The pictures were largely reminiscent of those western plains and mountains from which so many of these fine young sailormen had come. Certainly there was nothing to conjure up in that quiet hour the sights or sounds of war—and yet—once—the glint of the lantern that flashed along a pair of 12-inch rifles that stretched their black forty-five feet of length ominously above the screen "Yes" I thought, "these are perfectly consistent with the restful scene that flickers on the canvas below Guardians of the peace they are—pledges that 90 millions of people, peace-loving and prosperous, are determined that their peace and prosperity shall endure through the years to come, unbroken and unassailed!

An Opportunity for the Farmer in the United States

THE profitable cultivation of basket willow in the United States is an opportunity that should not be overlooked by farmers who are anxious to add to their income by the cultivation of a crop on land that is now lying idle. Basket willow, like a number of other farm crops, is one of the smaller opportunities so often lost sight of in the general desire to grow crops on a large scale with the thought that there will be corresponding large returns. American farmers are apt to overlook the combined results from many small crops that can be handled with comparatively small expense European farmers keep a strict account of these, and in the aggregate often reap a rich reward for their thrift.

The demand for basket willow as an article for manufacturing basket ware and furniture is constantly growing. In this connection it is interesting to know that the United States is a very large purchaser of basket willow rods from France, Germany, Holland, Belgium, and Austria, while there are millions of acres of waste or undeveloped lands in this country capable of producing enough basket willows to supply the world There is an annual importation of approximately one million pounds of basket willow rods ready for the basket-makers' use. Approximately four times this amount is imported in the form of manufactured basket ware and willow furniture. The total value of this material is about $300,000, which might as well be paid to the American farmers if they knew how to grow the crop successfully.

That the growing of basket willows is a profitable farm crop may be seen from the figures of yield contained in a United States Forest Service circular entitled "Practical Results in Basket Willow Culture" An acre of well-managed basket willows, calculating the yield at 3,000 pounds of dry sap-peeled rods at 5 to 7 cents a pound, will give a net profit of from $75 to $135 per acre. The cost of cultivating and harvesting basket willows is variously estimated at from $50 to $75 an acre. Of course the above figure of yield is above the average for the United States, but even if the crop should be only two-thirds of that obtained on the experimental farm at Arlington, Virginia, the net profit would still be far better than that of most other farm crops.

What Would it be Worth to You

If, by a series of swift key-strokes, you could verify your postings in a few minutes each day;

And by the same means extend and check all incoming and outgoing bills in a small part of the time it takes to do it mentally;

Figure inventories with fractions, angle and chain discounts, two or three times as fast; extend piece-work payrolls, prorate costs—all accurately with one machine?

Fire Chief CROKER says of The DAHLSTROM PRODUCTS—

At the International Municipal Congress and Exposition, Chicago, September 29th, *Edward F. Croker, Ex-Chief of New York City's Fire Dept. who spent 27 years in the service, 12 years as chief, said:*

"IF we are to better conditions, we must realize that 'fireproof' is not fireproof" as it is understood today. The literal definition remains, but many crimes have been committed in its name.

There is but one principle to fireproof construction irrespective of the kind of structure. To have fireproof buildings, architects and owners must throw aside precedence and eliminate the use of combustible and semi-combustible materials in their construction

. . . . . If there were still an absolute necessity for its use, if it could not be replaced with steel, as it has been in many modern constructions, it would then be well to attempt to conceive of something better I am opposed to the use of wood in any form in fireproof buildings and the law ought not to permit its use.

To me there is a fascination about steel interiors. It constantly emphasizes the absurdity of fire-fighting, for how can fires rage if they have nothing to feed upon?"

Interviewed, Ex-Fire Chief Croker said, "You are at perfect liberty to use my talk partially or entirely and apply it to your products I have watched your development since you first originated cold drawn steel interiors with great interest. I have nothing more to say My address and the fact that my private residence will be equipped throughout with The Dahlstrom Products is as strong a recommendation as I can make."

Ex-Fire Chief Croker's interview does not refer, does not include, any of the Dahlstrom doors now in use for the safety of the Equitable Building. A. C. They remain for storing securities the enormous value of all combustible materials in the building. A fair note to ask for the product, it must have in

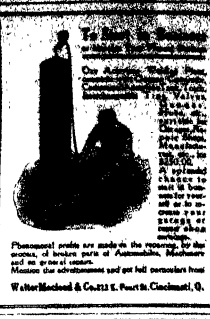
Notes and Queries.

Kindly keep your queries on **separate sheets** of paper when corresponding about such matters as patents subscriptions, books, etc. This will greatly facilitate answering your questions as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.



(12548) C A. E H says: I have seen it stated that the mouths of some rivers are higher than their sources. I can see that this may be true of rivers such as the Mississippi, which flow toward the equator through a number of degrees of latitude If the water is actually farther from the center of the earth at the mouth, will you kindly explain the force or forces acting upon it to raise it? A. All rivers which flow south in the northern hemisphere, or north in the southern hemisphere, are farther from the center of the earth at their mouths than at their sources The earth's diameter is 26 miles longer through the equator than it is from pole to pole The theory is that the earth was once soft and in rotation, and bulged at the equator by centrifugal force The earth has cooled and become solid, but the centrifugal force remains The yielding water takes the position which the rotation of the earth requires it to take The very definition of a level surface is one which is parallel to the surface of still water The Mississippi River flowing south does not take this position It is below that position at its mouth really down to the Gulf of Mexico, although in so doing it goes farther from the earth's center The name of the force raising it farther from the center of the earth is "Centrifugal Force"

(12549) A J I says: Kindly settle the following argument for me A friend of mine contends that after water has assumed the solid state as ice, provided the pressure is constant, its temperature will remain at 30 deg F as long as the temperature of the surrounding medium remains below 32 deg F and that if the surrounding medium was to go down to 8 deg F., the temperature of the ice would remain constant. I contend that the temperature of the ice varies with the temperature of the surrounding medium, as also does its volume A Water, in the solid state is no different from any other solid All solids rise and fall in temperature as the place in which they are is heated or cooled Every body knows that ice cream, which is largely frozen water, is cooled much below the freezing point and packed to make it keep Ice also expands and contracts by heating and cooling, just as iron or any other solid does People are misled by the fact that ice cannot be heated much above 32 deg Fahr. It melts, but so does every other crystalline solid when it is heated to its melting point All such substances cannot be heated above the melting point any more than ice can The peculiarity of ice is that it melts at a very low temperature Most crystals melt at a much higher temperature than does ice Ice when below 32 deg becomes dry It is easy to see the difference between ice cold air and ice in warm air The writer has cooled ice to the temperature of liquid air, more than 300 deg Fahr below zero It crumbled into very small pieces by its contraction at that temperature

(12560) A F H asks: Will you please explain through Notes and Queries, the following terms as applied to steel rails Horizontal Inertia, Vertical Inertia, Moment of Inertia, Section Modulus, Radius of Gyration? A Consult one of the books on mechanics, such as Merriman's "Mechanics of Materials," ($5 if ordered from our Book Department), for a full explanation Briefly, "moment of inertia" is a term signifying the sum of the masses of the particles of a body each multiplied by the square of its distance from the center of inertia which may be a point or an axis In the rail section herewith, the sum of the masses of the particles multiplied by their distances squared, would be the polar moment of inertia if all the distances ran together at

the crossing of the axes; or the moment of inertia about the horizontal axis, if the distances all ran vertically to the horizontal line *AA*, or the moment about the vertical axis, if the distances ran perpendicular to that axis. The section modulus is the moment of inertia divided by the distance of the most distant particle from the pole or the axis of inertia. Its value, like the values of the moment of inertia, may be found in the pocketbooks, for all standard rail sections. The radius of gyration is the distance from the pole or the axis (as the case may be) of inertia to that point at which, if all the mass of the body were concentrated, the moment of inertia would be the same as for the original shape.

Phenomenal profits are made on the repairing, by the process, of broken parts of Automobiles, Machinery and all grades of castings.

NEW BOOKS, ETC.

PRINCIPLES OF PHYSICS. By William Francis Magie, Ph.D., Henry Professor of Physics in Princeton University. New York: The Century Company. 1911. 570 pp.

The author's name is sufficient guarantee for the general excellence of the book before us. It is very remarkable how much information has been condensed into a volume so small, considering the boundless scope of the subject. Moreover, the information is thoroughly up-to-date. In turning over the pages we have found the Brownian movement and Perrin's recent work duly considered in their relation to the kinetic theory. Similarly the chapter on "Electricity and Matter" presents in simple but clear terms some of the fundamental facts upon which the modern views on the subject are based. A brief note is also devoted to the phenomenon of radioactivity There is little criticism to offer. The opening paragraph of the first chapter attempts a definition or description of "physics," and can hardly be said to be quite successful There are some things that can not be rigorously defined, and probably the scope of physics is such. One is almost tempted to say that "physics" is all science which has not been for one reason or another (not necessarily a very good reason) been given some other name —and even that may be physics One can not help regretting that it should be necessary or desirable in a book of this kind to avoid the use of the calculus, often at the cost of much complication in work can be done in elementary physics with a small stock in trade of the methods of the calculus, that it would seem well worth the while to arrange the student's courses in mathematics in such manner as to avoid the necessity of working out from first principles every case of 'proceeding to a limit." In the development of the absolute temperature scale, the ideal gas is introduced as a "guide" for the choice of the temperature function which shall enter into the expression for the efficiency of a heat engine It appears preferable to develop this function without reference to any specific properties of the working substance Making use of an "ideal gas" (which does not exist) gives an appearance of unreality to the argument, and is apt to leave in the mind of the young student an impression that the argument in some way depends on the properties of the "ideal gas," whereas what one is particularly anxious to impress upon the learner is the fact that the efficiency is wholly independent of the properties of the working substance. The general scope and arrangement of the book may be gathered from the main headings, which are as follows Book I—Mechanics 1 General Notions About Forces 2 Statics 3 Dynamics 4 Mechanics of Liquids. Book II—General Properties of Matter 5. Gravitation or Mass Attraction. 6 Elasticity 7 Capillarity 8. Gases 9 Friction 10 Diffusion Book III—Sound. 11 Sound and Sound Waves 12 Sounding Bodies. Book IV—Heat. 13 Temperature and Heat 14 Thermal Relations of Bodies 15 Heat and Energy Book V—Light 16 Geometrical Optics 17 Physical Optics Book VI—Magnetism and Electricity 18. Magnetism 19 Static Electricity 20 The Electric Current 21 Electricity and the Ether 22 Electricity and Matter

BUNGALOWS Their Design, Construction, and Furnishing With Suggestions also for Camps, Summer Homes, and Cottages of Similar Character. By Henry H Saylor Philadelphia The John C Winston Company 4to, 188 pp; illustrated Price, $1.50 net.

Bungalows, springing up mushroom fashion all over the land, have imparted a not unpleasing variety to our domestic architecture Mr Saylor's papers are aptly introduced by Burgess Johnson's "Bungal-Ode." The advantages and limitations of the true bungalow are impartially set forth, and under the heading "Types" we are given, in beautiful plates and succinct description, more than a score of houses scattered from the Atlantic to the Pacific coast Bungalows for seacoast woods, and hills are given separate consideration, and chapters on "Plan," "Foundations," "Walls," "Roofing," and "Interior Finish" tell what the prospective builder needs to know Even the fireplace, furnishings, lighting system, water supply and sewage disposal are treated at some length, and the setting of flowers, vines and shrubs, an important matter from an artistic point of view, is the subject of a final chapter The large pages, fine paper, clear plates and good printing make the book a desirable one to own, and the common-sense manner in which the author presents his knowledge and advice places the seal of practical value upon what would still be a work of beauty and suggestive inspiration even without so informing a text

PRACTICAL SILO CONSTRUCTION. By A. A. Houghton. New York: The Norman W. Henley Publishing Company, 1911. 69 pp.; 20 illustrations. Price, 50 cents.

We have before taken the opportunity to mention favorably the earlier issues of these "Concrete Worker's Reference Books." The treatise in hand, No 3 of the series, comprises directions for constructing concrete silos of various types. Full data and working drawings are given, and segmental forms and molds are shown for the building of monolithic and block silos.

Every Man Who Owns A Razor

Every woman who owns a knife—Every man, woman or boy who owns an edged tool—will never realize what smooth, keen cutting sharpness is until

CARBORUNDUM Sharpening Stones

demonstrate it—

Carborundum is the most remarkable sharpening agent the world has ever known.

Hard and sharp and fast cutting as a diamond—smooth and velvety as the finest natural stone.

Made into hones and sharpening stones of every size, shape and grade—for every possible sharpening need.

Here are a few Carborundum specialties that ought to be in every home—

No. 103-F Razor Hone—very fine—wonderfully efficient—in neat box $1 00
No. 79-F Knife Sharpener—Stag Horn Handle—solid stick of Carborundum—Octagonal in shape—in satin lined box 1 00
No 107-F Round combination stone for sharpening carpenters' tools 1 00
No. 149-F Pocket stone in neat box 15

Ask your hardware dealer—If he doesn't have them, send direct

Aeronautics

Death of Edouard Nieuport.—M. Nieuport, the builder of the fastest monoplane in the world, died from a fall sustained on the 15th ult. An account of his and other fatal accidents, together with a description of his monoplane, appears in the current SUPPLEMENT.

Helen's Record for the Michelin Trophy.—Emmanuel Helen, on a Nieuport monoplane, flew 1,252.8 kilometers around a 104.4-kilometer circuit on the 8th ult., in France. Deducting from his total time—14:07.50—the six stops he made, his time in flight was 13 hours and 17 minutes—an average speed of 58.6 miles an hour. His previous record of August 26th was 700 miles in 13:47:19.

The Aviation Meet at Nassau Boulevard.—The international aviation meet on Long Island was successful, and resulted in several new records. Chief of these was the record of endurance with two passengers, which was raised from the 1 hour 38 minutes 40 seconds made by Mamet at Rheims in 1910, to 3 hour 54 minutes 22 2/5 seconds. The new record was made by Lieut. Milling, in his Wright biplane, and in making it he also won a prize of $1,000 offered by the Hotel Knickerbocker for 100 minutes in the air with two passengers. The best previous American record, made by Beaty at the Chicago meet, was 1 hour 18 minutes 22 seconds. Besides races between Sopwith, on a Blériot, and Grahame-White, on his Nieuport, exhibition flights were made by Dyott on two Deperdussin monoplanes and also by Mlle Helene Dutrieu, on her "baby" Farman biplane. Miss Matilde Moisant outflew Mlle. Dutrieu by soaring to a great height in her Moisant monoplane, and flying far across country, while Miss Harriet Quimby made a record cross-country flight in 39 minutes, ascending to a height of 2,500 feet.

The Transcontinental Flight.—After delays of three or four days, owing to breakages and unfavorable weather conditions, the two aviators who attempted to cross the continent in opposite directions in Wright biplanes—Robert B. Fowler and Calbraith P. Rodgers—finally resumed the flight on September 28th. Fowler had twice previously tried to scale the Sierras, but without success. In one of these attempts he experienced difficulty in climbing to the necessary elevation, while in the second one, after attaining a height of nearly 7,000 feet and getting to a point within 15 miles of the summit, his motor stopped and he was obliged to glide back to a suitable landing place. He alighted at Emigrant Gap. His third attempt, on the 28th ult., resulted in reaching an altitude of but 1,500 feet on account of choppy cross currents of 20 miles an hour or more which drove him back to earth after a 20-minute flight. After this experience Fowler abandoned the race.

Rodgers's Progress in the Flight Across the Continent.—Rodgers's machine was so badly damaged by contact with a barbed-wire fence on the 24th ult. that nearly four days were required to repair it. He left Red House, N. Y. (where the accident occurred) at 10.35 A. M. on September 28th and alighted on the race track at Meadville, Pa., at 12:20 P. M., after having covered the 104 miles from Salamanca to Meadville in 106 minutes. This included circling the former town and hovering above Meadville at a 3,000-foot elevation for several minutes in an endeavor to locate the Country Club. About 10½ gallons of gasoline were consumed on the trip. A fresh start was made at 1:20 P. M. but the aviator was obliged to alight shortly after at Warren, O., on account of the oil tank not having been filled by his mechanics. A skid was broken by a concealed ditch and it was 4:30 P. M. before he set out for Akron. He covered 30 miles to Kent, a small place some 10 miles from Akron, in 40 minutes and was able to alight successfully in a field which he was barely able to discern on account of darkness setting in. He covered 204 miles altogether. During the next four days he made some progress and reached Huntington, Ind., 142 miles from Chicago. In starting on October 3rd, a down current drove him to the ground and smashed his machine once more. On the 5th he resumed the flight and covered 133 miles to Hammond, Ind.

Science

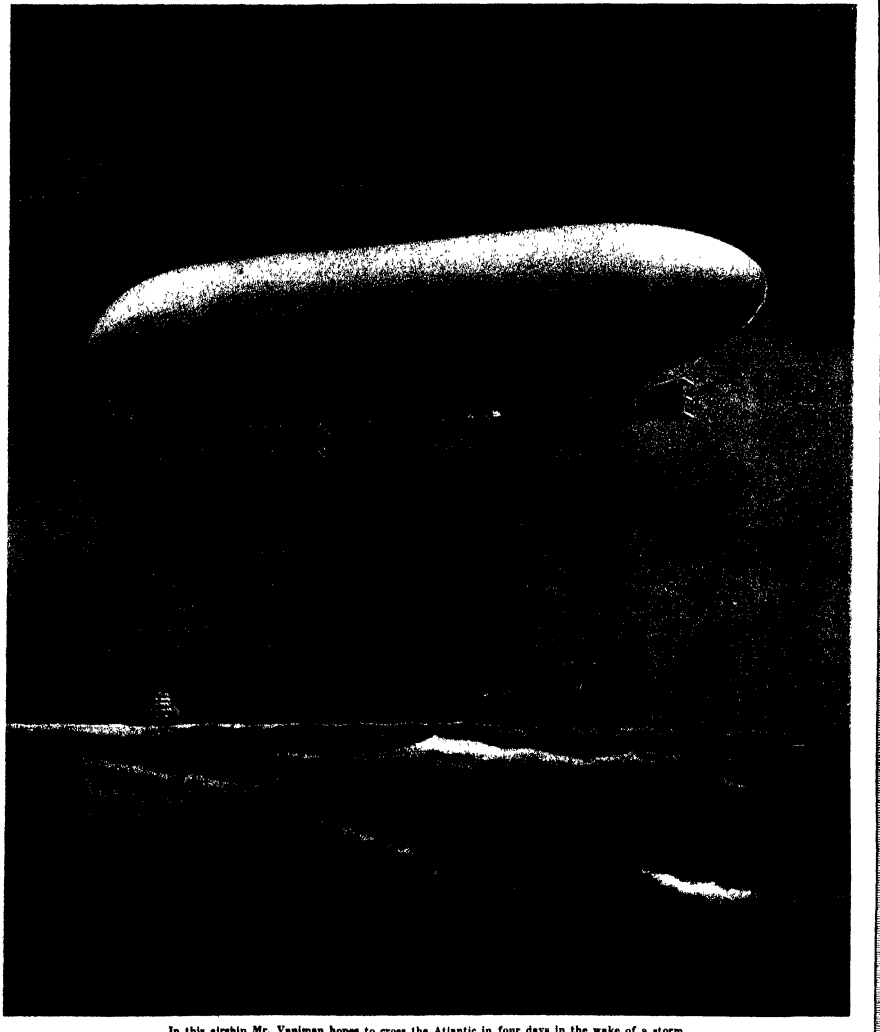
Constituents of the Body.—Our body may be said to weigh about 70 kilograms, or say 154 pounds average, the various constituents being as follows:

	Kg.	Lbs. av.	Per cent.
Muscles	30.4	67.02	43.5
Fat	13.3	29.33	19.0
Skin	12.4	27.34	17.8
Bones	12.2	26.90	17.5
Brain	1.6	3.31	2.2
	69.8	153.89	100.0

There are 45 liters = 45 kilograms or 99 pounds average of water and 25 kilograms = 55 pounds of solid matter; the latter being composed of 14 kilograms = 30.8 pounds of albumen, 7 kilograms or 15.4 pounds of fat, 3½ kilograms or 7.7 pounds of salts, and 0.7 kilograms, or 1.54 pounds of sugar.

The Work of the Human Heart.—The average human heart is a suction and force pump of remarkable capacity and durability. Each of its two chambers contains, on an average, 75 cubic centimeters or 4.575 cubic inches; the total contents of 150 cubic centimeters or 9.15 cubic inches being discharged 81 times a minute, corresponding to a delivery of 12,150 cubic centimeters (12.15 liters) or 741 cubic inches per minute, 729 liters or 25.73 cubic feet per hour. Expressed in U. S. gallons, the average human heart pumps through it each hour 192.6 gallons; each day, 4,622.4 gallons, each year 1,687,176 gallons; and in the adult life time of a man living to the age sung by the Psalmist 8,435,880 gallons. The pressure against which this fluid is pumped is equivalent to that of a water-column 2½ meters or say 8 feet 2.42 inches high; otherwise expressed, about 0.242 atmospheres or 3.55 pounds avoirdupois per square inch.

Strength of Human Bone.—Fortunately the human skull, although composed of bones is elastic—much more so than one would think. The average male adult skull, in fact, is so elastic that it may be compressed laterally in diameter by a blow or by pressure, applied at the center of area, at right angles to the surface at that point by 1½ centimeter or about six-tenths of an inch; recovering its original diameter and form, without breakage. The material of which our bones are made is so highly resistant that a cylindrical piece thereof only one square millimeter or 0.00155 square inch in area (i. e. only 1.128 millimeter or 0.044 inch in diameter) has a tensile strength of 15 kilograms or 33 pounds avoirdupois, figuring out at about 21,300 pounds per square inch. A similar sample of hard wood tested in the same manner held only 10 kilograms—that is, bone has 50 per cent more tensile strength than wood. A single bone fiber is shown in the Hygiene Exhibition, Dresden, supporting a weight of 5 kilograms or 11 pounds avoirdupois.



Change in the Habits of Wild Rabbits.—German natural historical periodicals are calling attention to an interesting change in the habits of wild rabbits, especially in the western parts of Germany, as for instance, Westfalen. The animals in question are giving up their ancient habit of burrowing, and have commenced in great part to imitate the hares, which, as is well known, nest only above ground. The hares themselves were once burrowers, and gradually went through the same change in habits in this particular that appears to characterize the rabbits at the present day—at any rate in Germany. In woods where the undergrowth is thick, and which are therefore especially suitable to the rabbits, they find hiding places in plenty for their nests; and even in open country, unwooded—and the rabbits seems to be taking more and more to the open—they take refuge in board-piles, rubbish-heaps, brush-piles, brick-kilns, drain-pipes, and ditches that are overgrown with weeds. The female makes little fortresses for her young, to protect them from the cannibalistic propensities of the male; she lines the nest warmly with fur from her own breast, visits them secretly at night, and perhaps suckles them once more during the 24 hours; but each time that she leaves them she carefully piles rubbish before the opening which leads to her defenseless family, and defies the obstructions with ordure.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are strictly first class, the articles well written, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Popular Science

IT was Huxley, we believe, who expressed the opinion that it was the duty of every scientific man to scatter among the multitude a few grains of that scientific knowledge which he has laboriously acquired by patient research. Huxley himself practiced what he preached, for he gave the world the most ably-written popular scientific essays in the language, essays which stand to-day not simply as admirable examples of scientific reasoning, but as almost classical examples of good literary English. Indeed, the whole group of Darwinian disciples seems to have been gifted with the rare ability of presenting the facts of evolution, so that the mass could understand them, and doing so without loss of dignity. Perhaps it was because the acceptance of the theories of evolution conflicting though these did with the accepted theories of creation, had come rather from the people than from scientific men, that the popular writers on evolution directed their appeals to the men and women who had no scientific knowledge and who had to be talked to in their own language. Certain it is that "The Origin of Species" could hardly have been written more simply and more lucidly than it is.

That science, when it is popularly expressed, need not be sensational, need lose nothing in accuracy of statement, and may be even artistic in expression, is evidenced by the written work of Sir Oliver Lodge, Sir William Crookes and Sir Norman Lockyer. English men of science, on the whole, are better literary men than Americans. In this country we find, frequently, obscurity and carelessness of expression which can only be explained by the lack of that literary atmosphere with which the names of Cambridge and Oxford are inevitably associated. It may be that our violently sensational press which seizes upon the artificial germination of frogs' eggs and converts it into a double-page Sunday magazine "feature" that causes a real scientific man to writhe at its mere contemplation, has brought about this aloofness of the American scientist from popular science. In no country in the world is the thirst for knowledge so great as here. In no country are the people so willing to read articles on scientific subjects, if they are only expressed in an untechnical way. As we glance through even the popular scientific periodicals, we find them almost deliberately technical in expression. Sentences bristle with references to the "Huntingdon-Heberle process," the "Kerr effect," and the like. Engineers are particularly given to this method of expression, which, however intelligible it may be to the scientist interested in that particular branch of research, is cryptic to the ordinary reader. What can the man in the street be expected to know of the X-Y-Z-type motor, and such terms?

There can be no doubt that coupled with an actual thirst for knowledge is the appeal of the miraculous. Unfortunately, it is the miraculous only that is exploited in the daily newspaper and if the particular scientific discovery of the day is not sufficiently startling for journalistic purposes, the reporter will not hesitate to exaggerate, if it is merely for the purpose of astounding his readers. It cannot be denied that there is a romance in science, a poetic quality that can be legitimately expressed, and which is expressed by the best writers of the day. What, for example, can be more appealing than the thought of Caroline Herschel assisting her brother night after night in his astronomical work, even feeding him with her hands so that he might not be compelled to lose a single precious moment? What can be more dramatic than the fact that Newton, when at last he beheld the law of gravitation in his grasp, was unable to complete the simple calculation that inevitably proved the correctness of his views, so overpowering was the effect upon his imagination? What poet has ever soared to greater heights than Darwin and Spencer, men who reared upon the thousands of biological facts that picture of the evolution of all living matter that is epic in its magnitude? What can be more magical to the ordinary reader than the simple story of the coal tar dyes, that wonder working of the chemist which has converted what was once a noisome ooze of gas works, difficult to dispose of, into a palette of gorgeous colors, a medicine chest of precious healing unguents, an arsenal of explosives, a garden of roses? What man is so unemotional that he cannot be stirred by the recital of Edison's quest of a filament that would give him the light for which he was seeking, a quest during which men slept in his laboratory with resistance boxes for pillows and work benches for beds?

In a paper read last year before the section of Physiology and Experimental Medicine of the American Association for the Advancement of Science, Prof. Charles Sedgwick Minot speaks of technical articles which are "bungled in form and weakened by prolixity." It is his opinion that the heads of laboratories should insist, by example and precept, that all the workers under their influence, should write clearly and briefly. "For if an author fails to show respect for his own scientific work, how can he expect others to respect it?" Surely there can be no better way of intensifying the world's respect for science than by using the English language for the dissemination of knowledge in a dignified and yet simple way.

Popular scientific writing, in its best sense, by which is meant simplified and not sensational science, implies nothing that a really scientific man would not care to undertake. It is all a matter of expression, of writing down to the level of the multitude—not necessarily speaking the language of the street, but at least appealing to the brain of the street. It is writing such as this which has proved a source of inspiration to many a man who has later graced the laboratory and the observatory.

Aircraft in the Recent German Maneuvers

AS in France, so in Germany, aircraft have been employed in the army maneuvers this year for the first time in real earnest—not as an experiment, but as a legitimate branch of the regular service. This feature was emphasized even more in Germany than in France, because no civilian aviators in disguise were employed, but only the official military pilots, all officers trained at the military flying grounds in machines belonging to the army.

As it happened, these maneuvers demonstrated principally that, for military purposes, the shortcomings of to-day's aircraft count for less than elsewhere; for the weather was very propitious during the more important military operations. Aeronautics is evidently sufficiently revolutionary in warfare; this existence simply means that fair, quiet weather at any moment entirely reverses the situation as it may have developed while stormy winds prevailed.

In this year's maneuvers Count von der Golz, the Commander of the "blues," had at his disposal the older but entirely reconstructed Gross-Basenach airship "M II," and four biplanes, all of the German Albatross-Farman type. All these aircraft flew a blue-white flag, and the "M II," had a new envelope of silver-gray aluminium-rubber cloth, which, without being heavier, is much more gas-tight and weatherproof than ordinary yellow rubber cloth. The red army air squadron, at the disposal of Prince Friedrich Leopold, flew a white-red flag and consisted of the fast "M III." Gross-Basenach dirigible and four "Taube" monoplanes. The "M III" still had its old yellow envelope, which in the end caused its destruction by fire through its being an absolute non-conductor of electricity.

The homogeneous nature of each of the opposing airfleets also tends to give these German air maneuvers a more military and businesslike aspect than the French ones displayed. Each of the eight aeroplanes carried two men, a pilot and an observer, the very bird-like Etrich-Rumpler monoplanes being just as good passenger machines as biplanes. It will be seen that the red side had the faster craft. Each side organized an aeronautic field-park, consisting of one great "regulation" transportable airship tent (100 meters long), and four aeroplane tents. The former are very strong. They consist of a skeleton of steel masts and cables, covered with stout canvas. It takes twenty-four hours to pitch such a tent and half as long to break it up. The aeroplane tents could be pitched and struck in a very short time. They were transported, each on two automobile trucks. So it became possible that Lieut. Machenthun flew at dusk to the farmost line of outposts, and later, in the darkness, his tent was taken there too on its automobile train. He camped all night close to the enemy and at daybreak ascended and flew directly across the hostile position, while the automobiles "took flight" with the struck tent toward safety in the rear. Having but little distance to cover in reaching the enemy, Lieut. Machenthun thus, after very little time, was able to return with information of vital importance.

The most striking work of the aeroplane, however, was done on the red side. The military situation was such that the red army attacked at once in force, while the blue one was as yet scattered and showed a very weak front. An elaborate ruse was then resorted to, to "bluff" the reds. An officer of the general staff, pretending to carry a message on horseback to one of the blue commanders, allowed himself to be chased by red cavalry, and while in flight deliberately dropped a map with bogus positions showing great forces of the blues (who actually were still far away) marked upon it. The chart was recovered by the reds and in due course reached their commander-in-chief, who was much pleased with such a piece of booty, especially as cavalry scouts reported that the marked positions really existed. The reds were presently massed against empty ditches containing small heaps of stone and earth, which, from a distance, appeared to the scouting cavalry as the yellowish-gray, helmet-covers of infantry prone on the ground, while positions actually threatened were denuded of troops. To make doubly sure, Lieut. Canter's monoplane was sent flying over to the enemy's charted positions. His observer (long trained aboard captive balloons) had hardly passed the hostile advance posts, when he discovered the true nature of that first line of bogus positions. Instead of returning, the officers first continued their flight until they had found that the second line was a mask as well as the first, that the reserves were not where they had been marked on the captured chart, and that the only real strength at that front was strong bodies of artillery. But the time now had become pressing, and it was of the utmost importance that the red commander should be informed of his error at once. Lieut Canter did not have to fly far in a search for the red headquarters. He spied the black-and-yellow flag marking the position of the Emperor himself, and with quick decision he laid his course for it, came close to the ground and had his observer drop a card with the news right before the feet of the Emperor. The reds then won, and later, at the criticism that always follows operations, the Emperor asked for Lieut. Canter, shook his hand and thanked him personally. In his final criticism the Emperor dwelt especially on the excellent services rendered by the dirigibles and aeroplanes, which proved to be the decisive factor in these maneuvers. It was observed that the fast dirigible "M III." employed peculiar well developed tactics in dodging artillery fire by sudden changes in the level and direction of its flight. On both sides the dirigibles were in action all day long.

Horses Hold Their Own in France.

NOTWITHSTANDING the fact that the development of the automobile, as well as of the aeroplane, has proceeded more rapidly in France than in any other country, the use of horses seems to persist there better than in some of the slower-moving nations.

In ten years the number of horses in Paris has diminished by 24,210—that is, from 96,698 in 1901 to 72,488 in 1911. This large decrease (a trifle over 25 per cent) makes the increase for the country as a whole all the more striking. In Paris mechanical traction has displaced the horse on all the omnibus lines, and the horse-cab is rapidly disappearing.

The persistence of the horse in rural France is attributed to the fact that there, in contrast with England and Germany, for example, the land is divided into very small holdings, so that the farmers are for the most part quite unable to afford an investment in mechanical appliances for traction, etc., notwithstanding the greater eventual economy in using motors in place of horses. It is expected that the farmers' associations will be able to devise some co-operative plans that will give the small farmer access to the advantages of modern inventions along this line.

Frank Julian Sprague

Inventor and Engineer

By Thomas Commerford Martin

THE career of a great inventor and engineer like Frank J Sprague, graduate of the Naval Academy and successful pioneer in the modern art of electric traction, stands out with peculiar distinction There may be, or may have been, notable sons of Neptune in other fields, but in the electrical he has certainly few rivals from the sea; and in the department of electric traction none. This is hardly to be wondered at, for it is a curious twist of fortune that takes a man from the trackless deep and sets him laying track all over the face of every continent.

On May 16th, Mr Sprague received from the American Institute of Electrical Engineers the Edison gold medal—its second award—for his achievements in traction, horizontal and vertical, and in accepting this new and rare honor, he remarked that the reason why he won it was that Edison had refused to keep him as an assistant in the early days of electric lighting The picturesque details will be noted a little later The point to be made here is that the cause or reason is not carried back far enough to be altogether adequate The fact is that when Sprague left the navy, there was no navy to leave The result was a general exodus carrying into electricity such men who have made their mark in it as Sprague, Greene, Duncan, Weaver, Shallenberger, and many another Had they had the new ships to command they would all have stuck to the ship, Sprague included, and someone else among them would now be the rulers of Taft's navy There would have been plenty of room for all their electrical engineering in the application and use of the modern diversified electrical equipment The advocates of peace and of a small navy ought not to lose this opportunity of showing, as they can irrefutably, that the absence of a fleet was the main cause of giving the world its useful trolley system Another cause, going just a little farther back, was that Mr Sprague was born in Connecticut

Winning entrance to the Naval Academy in a competitive examination, and graduating in 1878, Mr Sprague was already electrical in his tastes and aptitudes Even then he was inventing, and made a special trip to show Edison a new wrinkle in telephony Menlo Park was doing quite a little business of its own in telephonic invention, the details of which when brought to Mr Sprague's notice convinced him that he would have to get up rather earlier to catch the worms Nothing daunted—for every aspiring youth in those days invented a telephone—he took up gladly the duties of his profession, and sailed for the Far East on the old U S S "Richmond." While serving on the Asiatic squadron he acted as the special correspondent of the Boston *Herald* in recording the travels of General Grant and the wonderful reception given the old soldier in the Orient. This was congenial occupation to a man gifted with unusual powers of observation and expression—but the note books not used up in this fashion were devoted to data of all kinds of electrical theory and invention. The present writer has seen some of them and realizes what a nuisance Sprague must have been to his messmates. It may have been due to their intervention that he was shifted to the training ship "Minnesota," where his didactic qualities had full play. His next appointments were to the navy yards of Brooklyn and Newport. Farmer, the electrician, was doing his notable work for the torpedo station at Newport, and no one could come within touch of that noble spirit without being stimulated to thought and invention

Mr Sprague was greatly impressed with the possibilities of electric lighting, and at a time when no naval ship anywhere had the incandescent lamp, proposed to get away from the old methods so disagreeable and dangerous. He asked Edison for the loan of one of those long-waisted "E" dynamos, prototype of the modern skyscraper, but when he said that it was to be hitched to an antique single-cylinder fly wheel pump, Edison demurred. The irregularity of the pump engine might have made Sprague the inventor of the Ardois signaling system, but Edison had an intense aversion to seeing his lamps flicker Sprague let himself loose on new arc lamps, continuous current machines without commutators, and a double wound armature with internal field, the several circuits being connected to a field to give various series and parallel combinations. He was slowly finding himself That there was real inventive ability developing in the man is evident from the fact that in 1881, watching the action of a large Ruhmkorff induction coil, he suggested connecting the high tension coil to a balloon and the ground, and in case of discharge to get larger currents of low potential from the primary without using the circuit breakers Had he been master enough of his technique to "follow through" Sprague could easily have hit then upon the transformer.

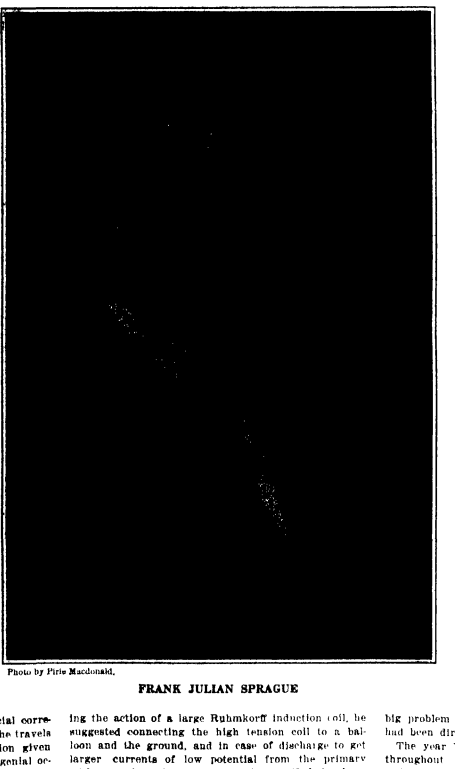

Photo by Pirie Macdonald.

FRANK JULIAN SPRAGUE

Then came the memorable Paris Electrical Exposition of 1881, and Sprague was crazy to get there He secured a detail to the U S S "Lancaster," bound for the Mediterranean as flagship, with leave at his own expense on his arrival abroad This in itself was an invention. The exhibition was closed, however, when the "Lancaster" passed the Pillars of Hercules; but as there was another electrical show in 1882, at the Crystal Palace, near London, young Sprague, by sheer nerve and audacity, got his leave extended, and landed in England with $20, an unnecessarily large sum for one so resourceful Taking up his work in connection with the exhibition—a landmark in English electrical history—he was made a member of the jury of awards, and at his own request was attached to the dynamo electric machinery section The section made him its secretary Here he was at once in his element meeting the great men of the day, revelling in the study of apparatus and free to ask any question that occurred to his preternaturally inquisitive mind In the midst of this delicious "joy ride," Sprague was peremptorily ordered to rejoin his ship at Naples, but though scared at the idea of a court martial, he bagged off, once more got leave, made a splendid report to the Navy Department on the exhibition and never went back That report is one of the very scarce electrical "treasure trove," and at once stamped Sprague as an engineer of quality In London Mr Sprague—barely an ensign yet- met Mr E M Johnson

'There is but one Edison and Johnson is his prophet,' said an English journal with equal truth and flippancy, and Johnson has always had a keen eye for talent He took kindly to young Sprague and sent him across the Atlantic to Edison just as he did that other distinguished leader, Samuel Insull This was May, 1883, and Sprague was ordered off to help in the construction at Sunbury, Pa., of the first overhead three-wire system of incandescent lighting That job was soon followed up by his being put in charge of the first three wire underground station at Brockton, Mass There Sprague made calculations for the distribution network of other Edison central stations then going on rapidly, but he regarded it as almost an impertinence to be bothered about them, for he was working out his first electric motor Here was the parting of the ways Edison has always wanted associates who were all his own, on whom his dominating personality could be impressed, who would help carry out his prolific ideas and not incidental inventions of theirs When Edison invited him to take up the subject of electric power transmission as an adjunct to Edison stations, Sprague replied airily and haughtily that he, too, had given a little thought to that, and meant to work it out from a personal point of view Needless to say, Sprague was invited promptly to resign With equal promptitude he did, organized his own motor company and in 1884 at the first American electrical exhibition in Philadelphia, made an enormous sensation by the exhibition of his new motors They not only gave a tremendous stimulus to central station development, as a source of supply of electrical energy, but set going a furore as to electric traction Sprague stationary motors for industrial power are in use to this day, but for the inventor the possibilities of the field were soon worked out, and he threw himself with redoubled energy on the big problem of transportation to which his thoughts had been directed ever since 1882

The year 1887 marks an epoch in electric traction throughout the world Sprague's first real street railway was that for St Joseph, Mo., but the vital point was reached when he took with confidence and even a light heart the contract to equip and operate a new system at Richmond, Va., with no fewer than forty cars All was crude but the goal had been reached, and with one great, mighty leap the trolley came into its own.

Meantime the Sprague interests had been consolidated into those of the Edison General Electric and the General Electric Company, with undoubted benefit to the public and the art, but leaving Sprague outside the breastworks They do say that his name was chipped off the castings The writer has never seen any evidence of such mutilation, but even if true it didn't make any difference; for Sprague was not chipped a bit On the contrary, he bobbed up serenely with a brand new system of electric elevators, and having tackled grades of 15 per cent blithely, now dealt deftly with those of 100 per cent Here Mr

New York's Fire College

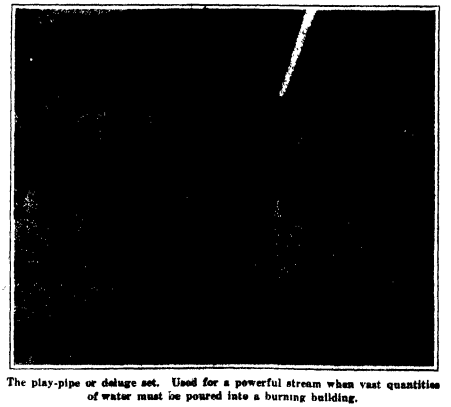
Fire-fighting and Rescue Work Reduced to a Science

By Herbert T. Wade

For many years the New York Fire Department has maintained a training school for firemen where practical instruction was given to those who had passed the civil service tests and had been appointed for a probationary period of one month. This training school not only was indispensable for the New York Fire Department, but served as a model for those of many other cities. To-day the need of thoroughly trained firemen is greater than ever, and their education can not be confined to such rudiments and essentials as may be taught to the probationer but in addition must involve systematic instruction all along the line up to and including the officers in command of companies and battalions.

In efforts made recently to raise even higher the standards of the New York Fire Department there has been established a Fire College which includes not only the various schools previously maintained by the department, but aims to extend and systematize the instruction in practical fire fighting, especially in the use of motor apparatus and other modern appliances now so extensively employed. This instruction is given by the best qualified men in the department and promotions to higher grades so far as is practicable are made only from those who have satisfactorily completed the appointed courses.

The chief of the department is the head of the Fire College Board, and the college itself is composed of a probationary firemen's school, engineers' school, officers' school, company school, and a special class in automobile operation. The first of these to be organized was the Probationary Firemen's School at which all the probationary firemen are required to attend for at least thirty days after their appointment and before they are regularly accepted and permanently detailed to companies. The instruction here as the illustrations show is exclusively practical, being based upon that formerly in vogue in the training school, but amplified as regards its amount and in the apparatus used. The practical work takes place in the rear of Fire Headquarters, where the probationers are marshaled with their scaling ladders of hardwood surmounted by a toothed hook and containing cross pieces up which a fireman may climb after the hook driven through a pane of glass perhaps is firmly placed on a window sill above. A number of scaling ladders in the hands of the firemen trained to their use affords a ready means of climbing up the side of a building and of passing from window to window. The probationers are taught not only the use of the scaling ladder, but to climb ladders of all forms used in fire fighting to raise and lower them, to straddle and stand on window sills, holding perhaps a companion in search of a point of vantage or passing along some inmate of the house who has been overcome by smoke.



The large ladders, some of them 50 feet in length and carried on the hook and ladder trucks, also are used in the school, and the life saving rope which is shot up to the roof by means of a gun and shot line. The firemen are taught to haul up hose and ladders by a rope and to lower persons to points of safety when stairways and fire escapes are cut off by the flames or smoke. This means that the firemen must know the various knots employed and the method of using the gun. Then there is the use of the life net, for perhaps no one is left on the roof to lower the fireman and he must learn to jump properly into the net held by his comrades. They, too, must know how to hold the net properly. All of this involves careful training for the muscular men who already have passed a severe physical test, and day after day they raise ladders climb up and down them to the top of the six stories of Fire Headquarters until they become expert. Then also they must learn the use of the hooks and axes for getting directly at the seat of a fire and removing smoldering wood, the use of picks, battering rams, crowbars, mauls, door openers, lock openers, tin roof cutters, wire cutters, and pinch cutters, all to get into a building or directly at the flames, for a fire may occur at night when a building is tightly locked. Furthermore there are the ordinary connections of hose, to make them speedily is one of the first duties of the fireman, and he must understand the making of siamese connections, taking a line from engine or high pressure hydrant to a standpipe, carrying hose into buildings, and up ladders, connecting with a cellar pipe, and finally the use of hose within tall buildings where the building pumps or the city high pressure may force water far above the limits of the fire-engine in the street below. The high pressure now used in the lower parts of New York city presents many problems and dangers for the hosemen, and this is a modern feature which the new system of instruction aims to make clear. The construction and use of the large special hydrants and reducing valves is demonstrated and the method of connecting hose thereto and the use of the nozzle holder are explained. There is also instruction in the use of the fire alarm telegraph system so that various alarms, ambulance calls, and other signals can be sent, and finally the Fire Department surgeons give an elemental but practical course in first aid to the injured.

Teaching the firemen how to stretch and connect hose and the use of nozzle-holders with high-pressure streams. A three-way connection with cut-off valves is shown in the foreground.

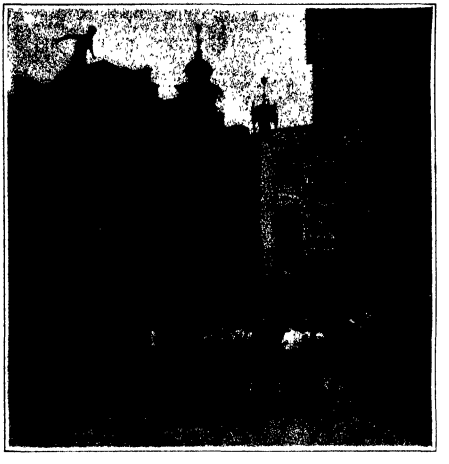
Using the cellar pipe. The platform represents a ground floor through which a hole has been chopped in order to get at a cellar fire with a hose stream.

The play-pipe or deluge set. Used for a powerful stream when vast quantities of water must be poured into a burning building.

NEW YORK'S FIRE COLLEGE

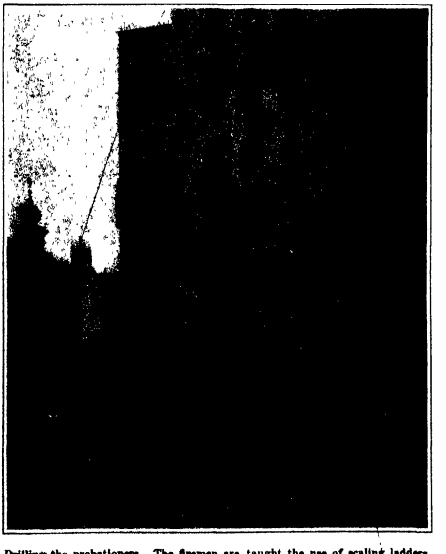
Interesting and important as this work is, it is perhaps exceeded in actual usefulness so far as the New York Department is concerned by other schools for the engineers and higher officers. Thus in the past there has been criticism of the engineers of the fire department that in some cases they did not keep their engines at a high degree of efficiency, and in actual operation they did not get the results that a more intimate and intelligent knowledge of the machinery would have secured. Accordingly a few years ago an Engineers' School was started with beneficial results, and this was made a part of the Fire College with a more extended course and competent instructors. In the high pressure districts the engineer of a company is stationed at the hydrant watching the control and reducing valves, while with the extensive introduction of motor apparatus now in progress he will be concerned with the care and operation of the gasoline engines. In the first place all engineers are required to attend this school, which is open also to first and second grade firemen upon approved application.

Hereafter only graduates of the school will be appointed as engineers. The practical work is being done in one of the machine shops of the department and consists of an extended course in engines and boilers and gasoline motor engineering. Here the engineers and firemen desirous of promotion study the actual machines and their construction and operation.



For many of the engineers, not to mention the firemen, gasoline motors have been a sealed book, but under the administration of Commissioner Johnson much motor apparatus is being added to the New York Fire Department and eventually the entire department will be on a motor basis, so the importance of the work is evident. In fact so immediate is the demand for properly qualified chauffeurs belonging to the uniformed force and men competent to operate and repair gasoline

engines, that there has been established a special class at the repair shops of the department for the training of such firemen. Here the men are taught the practical operation of motor apparatus so that competent chauffeurs will be forthcoming as the horse-drawn apparatus is displaced. This is taking place as rapidly as possible, and by the end of the year the New York Fire Department will have a number of distinct and separate types of motor-drawn machines in use.



The Officers' School affords a means of raising the general technical standard by having those who have evolved certain practical methods teach them to others, and give general information as to conditions and methods in different parts of the city. Thus chiefs and company commanders in the high pressure districts have learned to use this new weapon most effectively and gradually are standardizing the different practices. These must be taught not only to those serving in the protected territory but to others who may be called there either individually or with their companies in the event of a large fire. In other words, certain chiefs and firemen have acquired special skill in dealing with certain conditions, and it is the intention that such methods should be taught to every officer.

For the company school entire companies are ordered to Fire Headquarters and are instructed and drilled in the effective use of the apparatus.

The entire Fire College is intensely practical in its spirit, and its object of raising the general standard of fire work in New York city doubtless will be attained. With the practical work thus brought up to an even higher degree of excellence, it is likely that problems of construction and engineering eventually will be undertaken and the technical and professional knowledge of the firemen be correspondingly broadened, but to-day it is realized that efficiency alone is the keynote and this can be realized only through training and discipline.

The life net. Firemen being trained to jump into a net held by their comrades.

Drilling the probationers. The firemen are taught the use of scaling ladders and ropes for life-saving. The life gun and shot line to haul up a rope is the last chance for a fireman cut off by flames or smoke.

NEW YORK'S FIRE COLLEGE

Wireless Detectors

By Adelbert J. Gogel

ELECTRIC wave detectors, the most delicate part of the wireless receiving set, are the subject of much argument as to their relative sensitiveness and relative merits. There are a number of different types known, which may be arranged as follows in order of merit, according to most authorities:

(1) Electrolytic, (2) Peroxide of Lead, (3) Perikon (Chalco-pyrites and zincite), (4) Ferron (Iron pyrites), (5) Silicon, (6) Molybdenite (Molybdenum Disulphide), (7) Galena (Lead Sulphide), (8) Carborundum (Artificial Silicon Carbide).

The Electrolytic Detector, perhaps the most widely known type, appears in many forms, the most frequently used of which is that in which the point of a very fine silver plated platinum wire, about 0.001 millimeter in diameter, called a Wollaston wire, is immersed in a nitric acid solution contained in a small graphite-carbon cup. It is necessary to use a battery and a non inductive rheostat capable of very fine adjustment, called a potentiometer, in connection with this detector. The battery polarizes the electrolytic cell, that is, the fine platinum wire is covered with tiny bubbles of oxygen and then the resistance rises so high that the current is nearly reduced to zero. If then an electric wave fall on the aerial connected to the electrolytic detector, it suddenly reduces the resistance of the cell. A telephone receiver of great sensitiveness being connected in series with the cell and potentiometer, sound signals can be heard in the telephone. For general and long distance work, this detector cannot be excelled except in localities where high powered interference is very frequent, which causes the platinum wire to be dissolved very rapidly and a detector working on different principles must be substituted. Substitutes will be mentioned later. The Lead Peroxide Detector consists essentially of a pellet of lead peroxide clamped between two surfaces, one of lead and one of platinum. A battery, potentiometer and telephone receiver are connected with the detector in the same manner as with the electrolytic detector. The lead peroxide detector works on a new principle, although no acids or liquids of any kind are employed its action is electrolytic. When lead peroxide, lead and platinum are brought in contact as described it has long been known that lead will be deposited on the platinum surface. When a battery is connected up properly with the detector, it opposes this action and causes the lead to be deposited upon the lead surface. When an electric wave falls upon the wires connected with the detector, a sound in the telephone is heard because of the change of resistance brought about by the passing of a wave. The Perikon Detector contact is between crystals of chalco pyrites and zincite, in the Ferron Detector between a crystal of iron pyrites and a metal point, in the Silicon Detector between the element silicon and a wire, in the Molybdenite Detector between a crystal of molybdenum disulphide and a metallic surface, in the Galena detector between a crystal of lead sulphide and a very fine wire, in the Carborundum Detector between a crystal of carborundum or silicon carbide and a metallic surface.

The Silicon Detector retains its adjustment even when very near to a very high powered sending apparatus, and is therefore to be recommended where interference is very severe. If a piece of 99/100 per cent pure silicon can be procured, nothing better can be desired.

The Carborundum Detector, even though subjected to somewhat severe blows, often retains its adjustment for months at a time, which causes it to be the favorite detector with the amateur. However, it requires the use of a battery and potentiometer for its efficient use in long distance work. The green crystals are more sensitive than the blue or purple ones. The side of the crystal connected to the ground should be covered with tin foil or soldered in a cup.

A New York firm has put on the market a promising new detector for which broad claims are made. This detector is of the vacuum bulb type and very similar to the "Audion" of Dr. Lee De Forest which is not within the reach of the average experimentalist owing to its high cost. This detector consists of an electric light filament, a grid and a plate sealed in a highly exhausted bulb. A battery to light the filament and another battery and a rheostat capable of very fine adjustment are necessary for the operation of this detector. When the current to light the filament is turned on the detector is ready for business, requiring no adjustments of crystals and points or Wollaston wire and acid. This detector can be used to receive from all systems of transmission, singing spark quenched spark, arc sets, telephone sets in fact it will detect any wireless wave from whatever source it is produced. The makers of this detector claim it to be more sensitive than the electrolytic which will be a decided advance in wireless receiving apparatus.

The wireless operator should not content himself with one detector but should have several ready for use and a switch with which to connect up the desired one.

A device of some kind should be used to ascertain whether or not the detector of a wireless set is in a receptive condition. Several devices of this class are quite well known but a short description will not be amiss. If a key sounder and battery are connected up near the detector a sound is heard in the detector when the key is raised, if the detector is in working order. This method requires the constant operation of the key during the test or search for a sensitive area. But the author has found that if an ordinary electric bell with the gong removed or a buzzer, is connected with a switch and battery, and two or three feet of copper wire be connected to the interpreter, the arrangement is much more convenient and efficient. The short length of wire acts as an antenna, and owing to the speed of the vibrator, a continuous musical note is heard in the receiver when the detector is working properly.

A variable condenser of good capacity should be shunted around the detector enabling weak signals to be strengthened or cut out as desired. While transmitting, the detector should be short circuited by a switch to prevent its being burned out, or the wire in the telephone fused.

When not in use, the detector should be protected from dust and moisture. The crystals of the thermo-electric type of detector should be touched with the hands as little as possible for the oil secreted from the skin causes a marked decrease in the sensitiveness.

Vaniman-Seiberling Transatlantic Expedition

Preparing for the Second Attempt to Cross the Ocean by Airship

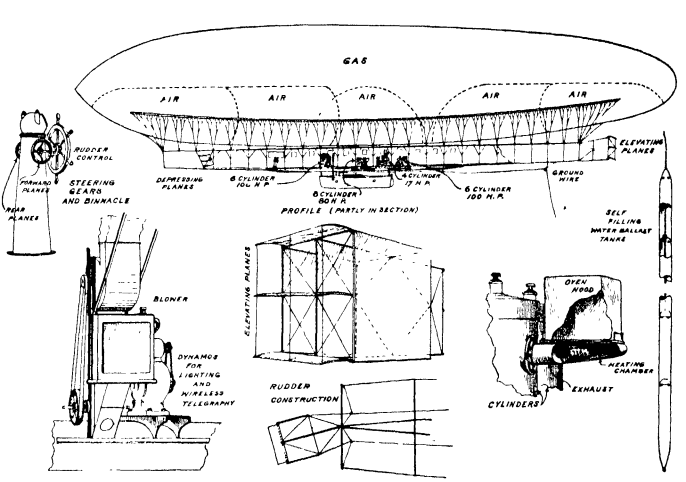
It was with no feeling of regret that Mr Melvin Vaniman, leaning over the taffrail of the steamship Trent watched the ill fated airship "America" sink slowly to the sea One might suppose that the engineer who had spent so many years of work on this dirigible would entertain some sentimental regard for the old balloon But Mr Vaniman's thoughts were on another expedition, in which he would not be hampered with old material, an old gas bag, and old engines, but could plan an entirely new airship made of brand new material exactly as he wanted it The "America" had served her purpose well, and from her in the years that had passed Mr Vaniman had learned the lessons that were necessary to make a future ship successful The design of this new airship was already beginning to take form in his mind, and after a short rest he was eager to begin the work again along new lines

When the "America" was abandoned it was structurally sound showing that the principles involved were correct One part only had failed, a key worked loose in one of the propellers, and to this defect Mr Vaniman attributed the failure of the expedition, as was pointed out in the SCIENTIFIC AMERICAN of October 28th, 1910 The propeller was one of a pair that could be revolved with their axes so as to exert a thrust at any desired angle Had he been able to use this pair of propellers to lift the machine bodily upward by power, he could have raised his equilibrator out of the water and prevented that terrifying and nerve-racking surging of the airship caused by the drag of the equilibrator in the waves during the storm Contrary to public opinion, Mr Vaniman's faith in the equilibrator, or its equivalent, was not shaken, of enabling the "America" to beat all records for dirigible balloons as to time in the air, distance traveled and weight carried Its action in the sea, its defects and good qualities were all known after this voyage, and it was from this experience that Mr Vaniman got to the heart of the problem, viz, the designing of a device that would serve the purpose of the old equilibrator and not have its defects, a device that would have a changeable weight not a fixed weight, in other words an equilibrator that could be made heavy or light at will

Principal Features of the Construction.

Early this summer Mr Vaniman succeeded in interesting Mr H A Seiberling, president of the Goodyear Tire & Rubber Co., of Akron, Ohio who agreed to furnish the necessary capital The construction of the gas bag was immediately started at the Goodyear plant and it was shipped to Atlantic City early in September The gas bag was built according to Mr Vaniman's directions and differs considerably from that of the "America" The "Akron," as the new airship is called, is longer but of smaller diameter, and tapers gracefully toward the stern The old hangar of the last year's expedition is being used by Mr Vaniman, and to use this shed without enlargement it was found necessary to cut out 10 feet from the envelope as originally designed The present length of the gas bag therefore, is two hundred and fifty-eight feet, while its diameter is forty-seven feet

Below the airship runs a car similar in shape to that of the "America," but, in the present instance, considerably longer The body of the car is a steel tank forming a reservoir for five tons of gasoline On this tank a platform is built, which is the deck of the airship To drive the airship three engines are provided One forward, of 100 horse-power rating, is fitted with propellers that rotate only in the vertical plane The next two engines, of 100 and 80 horse-power, respectively, drive the propellers whose plane of rotation may be turned to any desired angle Normally, only the forward engine will be used to drive the airship ahead, and it should give the craft a speed of about 30 miles per hour About 60 pounds of gasoline will be consumed per hour, so that the supply of gasoline should last about a week The propellers of the other two engines will be feathered, or turned to horizontal position, so as to offer no resistance to the forward propulsion of the vessel In addition to these engines, there is a 17 horse-power engine directly connected with a dynamo, which will generate current for lighting the airship at night and for operating the Marconi wireless telegraph apparatus. This engine will also operate a blower with which the ballonets of the gas bag may be filled Furthermore, it will drive a pump countershaft with which any one of the large engines may be started



Substitute for the Equilibrator.

"If we can only keep down," said Mr Vaniman in a recent interview, "our problem will be solved" It is an easy matter to design an airship to lift the necessary weight to enable one to cross the Atlantic The difficulty is to maintain the airship at a constant moderate elevation above the water The equilibrator performed this office last year This year Mr Vaniman expects to control the height of the airship mainly by taking on water ballast, and also by using stabilizing planes fore and aft In case of emergency the elevating and depressing engines can be used. There will be three planes on each side of the car, at the forward end, which, as indicated in our front page illustration and also in the accompanying sketch, are curved upward, while those at the rear, mounted on the rudder, are reversely curved These planes may be tilted to any angle desired, and will serve to keep the car on an even keel When dipping down to take up water ballast, the forward planes will be used for depressing the bow and the rear planes for elevating the stern These planes may be controlled separately by handwheels at each side of the binnacle, as indicated in one of the sketches The level of the vessel may also be controlled to a considerable extent by inflating the ballonets forward at the expense of those to the rear, when it is desired to make the bow heavier than the stern, and *vice versa*, when it is desired to make the stern heavier

To scoop up water ballast, it will be necessary to drive the balloon down near the level of the sea, which may be done by tilting either pair of the adjustable propellers to the proper angle. The only object in having two sets of adjustable propellers is to have a reserve pair in case of accident. The device with which the water ballast will be taken up is similar to the equilibrator used last year. It consists of tanks about 6 inches in diameter and 24 inches long, strung upon cables exactly as were the gasoline tanks of the equilibrator These water ballast tanks will be provided with openings near the upper end of each, so that by dragging them in the sea they may scoop up water There will be three sets of tanks strung on separate cables, and under normal conditions they will not hang from the car, as did the equilibrator, but will be stored in the body of the vessel.

When taking up the water for ballast, if the wind is strong, the airship will be headed into the wind and the tanks will be trailed from a point aft of amidships, so that there will be no tendency for the airship to nose downward into the sea

It is planned to maintain the airship at an elevation of between 200 and 1,000 feet at the outset of the voyage, but as the airship is lightened by the consumption of gasoline and the provisions, the airship may rise to much greater heights During the daytime it will have to be heavily water-ballasted in order to hold it down when the gas in the balloon is expanded by the heat of the sun At night this ballast will be poured out to compensate for the contraction and consequent reduced lifting capacity of the balloon

Some novel details of the airship with which the transatlantic voyage will be attempted.

Suspended below the car will be the lifeboat in which the crew of the "America" made their escape This will be materially changed to facilitate launching and for the comfort of the crew There will be no well in the center, because there will be no equilibrator to pass down through it In this boat the wireless telegraph apparatus will be stored A much more powerful equipment will be provided this year, with a range of 500 miles, so that there will be little difficulty in keeping in touch with vessels along the course To provide a ground, a wire will extend to the stern of the vessel, and thence trail in the sea, as indicated in the front page illustration.

The Crew.

The crew of this expedition will consist of the commander, navigator and helmsman, a wireless operator, two engineers to keep constant watch over the engines, and one extra man for general work.

Provisions will be carried for a cruise of twenty days. An ingenious cooking stove has been provided. Last year, when at the close of the first day it began to grow dark, Mr Vaniman was astonished to find that the exhaust pipe of his engine was red hot and expelling streams of sparks that were invisible by day This year he has made a cook-stove on the exhaust, as shown in one of the sketches, and will utilize the heat for cooking

On the Wings of a Storm.

The construction of the airship is proceeding very rapidly and will probably be completed by the end of this month Thereafter, two or three trial trips will be made, and then, when weather conditions are favorable, the expedition will be launched. Mr. Vaniman expects to make good use of the storms that travel across the Atlantic to carry him over. It will be recalled that last year a storm was encountered which carried the airship along at such speed that

it had to drift broadside to the wind, owing to the drag of the equilibrator. This storm with the aid of the motors took the airship to a point near Nova Scotia, but then vanished, and a second storm which had been forming over Cuban waters for three days began to affect the airship, although 1,200 miles away The wind flowing toward the storm center was so strong that the motors could not be used, and the airship was taken southward out of its course. Had the "America" been able to lift its equilibrator and scud before the wind, it would have been carried more than half-way across the Atlantic inside of two days by the first storm; for the meteorological charts show that this storm traveled to within a few hundred miles of the other side before it was spent. As a rule, it takes from three to four days for a storm to cross from the western to the eastern shores of the Atlantic Ocean As is well known, the winds of a storm always blow toward the storm center. As a storm center moves up our coast, the winds blow toward it from the northeast, but when it passes beyond us out to sea, it is followed by westerly winds It is Mr. Vanlman's plan to start after a storm center has passed from 800 to 1,500 miles out to sea Then on the wings of a western wind, he will be carried toward this center, which, in the meantime, will be moving rapidly across the ocean. By driving his airship at the rate of 20 miles an hour, he will succeed in moving faster than the storm center, and he confidently expects to be able to cross the Atlantic, under such conditions, in less than four days

Navigating Instruments.

In connection with the airship expedition, Mr Vanlman has devised a number of interesting instruments which will indicate the direction of his travel and also his speed One of these consists of a combined camera and compass, the camera having its field divided into squares Noting how long a fixed object on the water below takes to pass across a given number of squares and knowing his height above the water, as indicated in the barometer, he will be able to determine definitely his speed over the water, and, by referring to the compass, his direction of travel The only fixed objects on the ocean are the white caps It will be recalled that, although waves travel, the water that forms them is practically stationary Hence the foam of a white cap may be considered a fixed object on which observations may be made In addition to this, Mr Vanlman has invented a sextant of an interesting type, for use on the expedition

Despite the sensational nature of the expedition, Mr Vanlman cannot be considered a mere adventurer He is intensely interested in mechanics and invention and in no other field does he consider that there are such possibilities as in the future dreadnought of the air the dirigible balloon

Electricity

Experiment in Purchasing Electricity.—The work of electrifying the lines from Lauban to Konigszelt is soon to be begun. The current for these lines will be bought from commercial electric power stations, instead of being supplied by a power station built by the railroad itself. The decision to purchase power was made in order to determine whether this would be a cheaper way of operating the line than if the power were generated by a station built especially for the railroad.

Telephone Precautions in Gas Works.—An investigation was recently made in Germany to determine whether any accidents had ever occurred in gas works by the ignition of gas with sparks from the telephone apparatus. No such accidents were reported, although it was found that gas could be ignited if it were projected upon the instruments while they were in operation Hence the Association of German Gas and Water Works has decided to permit the use of telephones in gas works, but requires that they be protected The bells, for instance, should be covered with a wire gauze guard

Restoring Sulphated Cells.—A method of restoring sulphated storage cells was recently described in the *Journal of Physical Chemistry* It is recommended that the cell be restored by charging it at the usual rate in a solution of sodium sulphate The sodium sulphate should be pure, and the best concentration is found to be 200 grammes $Na_2SO_4 10H_2O$ per liter A 60 hours' charge should be sufficient to restore the cell The cost would be exceedingly small as compared with the method now sometimes used, of charging the cell at half the normal rate for a long time in the ordinary battery acid

Cactus Telephone Poles.—According to a recent press report, the government is about to build a telephone from Tucson, Arizona, into the Catalinas, for the forestry service The building of the line will be rather difficult, owing to the rocky nature of the country, which will make it impossible in some places to set wooden poles of the ordinary type It has been proposed that in the canyons the cacti growing along the line be used. Brackets will be fastened to the cacti, and the wires will be supported on the brackets in the usual way. This type of pole may be adopted wherever cactus grows along the line, provided it does not require too much zigzagging

The Boston Electrical Show of 1912.—Plans are under way to make the electric show in Boston, from September 28th to October 26th, 1912, the largest electrical exposition ever held in the world The entire Mechanics Building in Boston will be used This building has 105,000 square feet of exhibit space, not counting the halls and aisles, and a seating capacity for over one hundred thousand visitors at one time It is hoped that this electric show will afford an impressive demonstration of the possibilities of electric development, particularly in New England There seems to be a wide-spread electric awakening in New England, which is extending beyond the cities to the rural districts as well.

Electric Cranking for Automobiles.—One of the prominent automobiles for 1912 will be equipped with a generator and storage battery normally used for lighting the lamps and igniting the engine, but with the generator so arranged that it may also be used as a motor to "turn over" the engine, thus obviating the necessity of cranking by hand. When the operator pushes the clutch pedal, a gear wheel on the electric motor will engage with teeth on the fly wheel, and the motor will be operated by current from the storage battery, to turn the fly wheel and start the engine When the engine starts the motor becomes a dynamo, and generates current to be used for charging the storage battery, and for ignition purposes.

Science

The University of the Philippines.—According to the *Manila Free Press* it is expected that Vice-Governor Gilbert will select several new members of the faculty of the University of the Philippines during his visit to the United States Physics apparatus to the amount of $2,500 has recently been purchased Several hundred students are now in attendance

Standard Time in Portugal and Her Colonies. Following the good example recently set by France, Portugal and all the Portuguese colonies will adopt standard time, in accordance with the recommendations of the Washington Meridian Conference of 1884 The change takes effect January 1st, 1912 Western European time (I e, Greenwich time) will be used in Portugal, the Islands of Principe and Sao Thomé, and Whydah

A Double Shooting Star.—The rare (if not unprecedented) observation of a double shooting star was made by the Abbé Verschaffel, director of the observatory at Abbadia, at Hendaye, France, at 3 17 A M July 22nd, according to a note published in *L Astronomie* The larger of the two components was eight or ten times as bright as Venus, and left a slight trail, it was followed at a distance of about four degrees by its companion, which was as bright as Venus Both objects were white They moved rather slowly from west to east

Prof. Schuster to Lecture at Johns Hopkins —A course of lectures will be given between October 16th and 28th in the physical laboratory of Johns Hopkins University, Baltimore, by Arthur Schuster, F R S, honorary professor of physics in the University of Manchester Prof. Schuster will discuss the cosmical applications of recent advances in physics explaining the methods of examining correlations between solar and terrestrial phenomena, and pointing out the problems in solar and terrestrial physics that seem to call for special investigation Meteorologists and climatologists will be interested to know that the lecturer proposes to disprove the existence of Ed Brückner's 35-year meteorological cycle

A Martyr to the X-Ray.—Dr Hall-Edwards, of the Birmingham University, according to the *English Mechanic and World of Science*, has not been spared the payment of a heavy price for the benefits he has conferred on mankind by his researches in X-ray photography A short time ago both his arms were amputated as a consequence of the dangerous experiments he had carried out He has just made the novel suggestion that photography should be included in the ordinary university course of training The connection between photography and art, he thinks has been overrated Nothing has helped science more than photography of late years, and it should, therefore, receive more attention than it does at present in the education given both in schools and in the universities.

The Telephone and the Phonograph.—A reproach which has often been raised against the telephone is that it leaves no trace whatever of the conversation transmitted. Thus, a telephone conversation can never figure in a law suit. It is not surprising, therefore, that for some time past efforts have been made to devise an apparatus by means of which a permanent record can be kept of the words spoken over the telephone, and the phonograph has often been thought of in this connection. According to a note reproduced in *La Nature* from *L'Elettricista*, Prof P Perotti has just scored a success in this direction The telephone receiver is composed of two loud-speaking telephones, one of these is furnished with the usual mouth-piece; the other is connected with the vibrating membrane of a Pathé phonograph The current required for this telephone is a little greater than for ordinary installations. The phonograph record can be made to reproduce the speech in the usual manner.

Engineering

A Tunnel Under the Yangtze.—It is stated, on the authority of the *London and China Telegraph*, that a report has been made to the viceroy of Kiangsu on the much-talked-of project of a bridge over the Yangtze River The report is said to be adverse to this project and to advocate a tunnel, as more practicable and much less expensive

A Year's Progress at Panama.—The total amount of excavation in the Atlantic, Central, and Pacific divisions during the fiscal year 1910-11 was 31,804,120 cubic yards There were excavated in the Atlantic Division 6,738,548 cubic yards. The total excavation in the Central Division was 18,522,692 cubic yards, of which 16,221,672 cubic yards were removed from the Culebra section, locally known as Culebra Cut, and the remainder—2,301,020 cubic yards—from the Chagres River section Excavation in the Pacific Division aggregated 6,542,915 cubic yards

Photographic Views of the "Liberté."—The photographs of the wreck of the "Liberté" show how similar were the effects of the explosion of her magazines to those observed on the "Maine" This is not surprising In both cases the energy of a large amount of explosives was suddenly developed at a point many feet below the surface of the water The resulting gases unable to escape through the bottom or sides of the ship being resisted by the incompressible water, expended their energy in tearing apart the decks above and folding them back, forward upon the bow, and to the rear upon the superstructure

The Latest Atlantic Liner —Not a great many years ago the new Anchor liner "Caledonia" the latest addition to the fleet of large passenger ships on the Atlantic would have been hailed as the largest ship afloat, but so rapid is the increase in length and size that a handsome ship of this class will slip into a port like New York on her maiden voyage with scarcely more than a passing notice She is 570 feet in length and at full load displaces 17,000 tons Built at the yards of D & W Henderson & Co., Ltd., she is not only the largest vessel launched from that yard but is the most up-to-date vessel possessed by the Anchor Line

Widening the Corinth Canal —The canal which cuts the Isthmus of Corinth was opened in 1893, its route being the same as that over which the Romans tried unsuccessfully to construct a canal in the time of Nero Although it shortens the journey from the Adriatic to the Piraeus by 202 miles this canal has been little used by foreign steamships, on account of its narrowness and the strong current which makes the passage dangerous and it has hardly been successful as a financial enterprise Operations have now been begun, however to widen the canal, so as to make it navigable for vessels of the largest size The cost of the improvements is estimated at $160,000

Advantages of Internal Gear Drive—The advantages of gears over chains as a motor-truck drive may be enumerated as follows The gears can be properly inclosed and lubricated and any range of reduction obtained The differential can be run at a higher speed and hence at less strain and higher efficiency than chains The bevel gear reduction can be made one to two while with the chain the bevel reduction is found to be in general one to three and one to four The former, therefore, is a more efficient bevel gear because the efficiency of the bevel gear decreases when the ratio of reduction increases The side swaying of cars causes chains to get out of line and thus increases wear The stretch of the chain must be taken care of from time to time by readjustment of the radius rods Both radius rods must be given uniform readjustment or the rear wheels will not run in line Few laymen can do this Bevel gears are at all times in positive relation to one another and do not require readjustment.

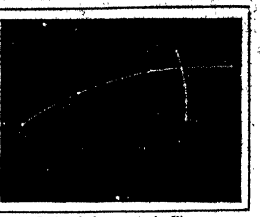


Diagram of Brooks's comet.

Three Comets Now Visible

Directions How to Find Them

By Prof. S. A. Mitchell, Columbia University

Path of the comets in Virgo.

TWO comets are now visible to the naked eye one in the evening and one in the morning sky, and a third one may be seen with an opera glass or small telescope if one cares to look for it

The year 1911 has been rather remarkable in that no less than seven comets were discovered in the nine months before the end of September The sixth comet for the year known in astronomical circles as comet *f* 1911, was discovered abroad on the evening of September 22rd, by Quenisset while the seventh comet or comet *g* 1911 was picked up on the morning of September 29th by Beljgawsky, making it the first comet ever discovered in Russia

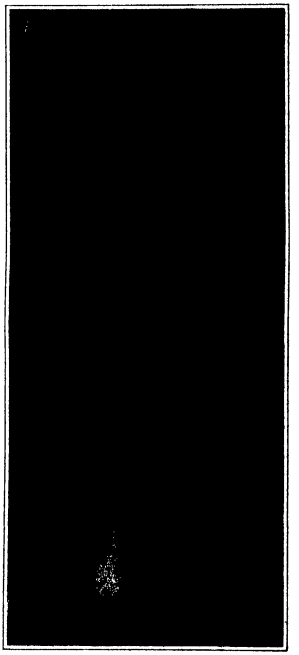
For a few days after the discovery it appeared as if Beljgawsky's comet were going to fulfill the wish for a brilliant comet expressed by the writer in SCIENTIFIC AMERICAN September 30th page 299 On September 30th, the morning after its discovery on a rather bright sky due to the coming of dawn, Prof Frost at the Yerkes Observatory saw the comet's nucleus as bright as Regulus the chief star in the "Sickle," with a tail 5 or 6 degrees in length Under slightly more favorable circumstances, the comet would probably have been as bright as Halley's, when this interesting visitor was present in the morning skies

Unfortunately however, the comet did not live up to expectations so that now we have not a comet in the sky so brilliant that all may see it without the aid of special directions

When a comet is discovered it is necessary to calculate its orbit and predict where it will be in future by the aid of an "ephemeris" As mentioned in the article on Brooks's comet (SCIENTIFIC AMERICAN September 30th) most of the orbits are computed on the assumption that the comet is moving in a parabola about the sun The position of the comet in space at any time depends on five quantities which are called the *elements* of the orbit The plane of the comet's orbit in space is defined by its relation with respect to the ecliptic, and it takes two quantities to express this One of these quantities is the line in which the comet's plane and that of the earth, or ecliptic intersect This is called the *line of nodes* The other is the angle between the two planes, or *inclination* When the comet crosses the ecliptic, passing from the south to the north side, it is said to be at the ascending *node* (symbol, ☊) To determine the direction of this line in space we need the longitude of the ascending node, which is the angle in the plane of the ecliptic from the vernal equinox to the ascending node

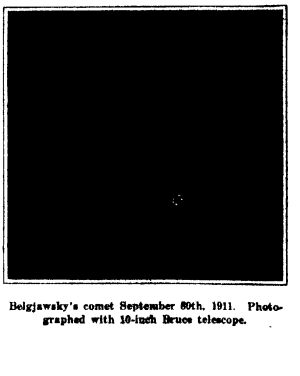
The third element needed is the direction of perihelion in the plane of the orbit This is called the *longitude of perihelion* and is the angle in the plane of the orbit from the ascending node to the perihelion point The fourth element is the distance of the comet from the sun when at perihelion, and the fifth the time at which the comet is close to the sun

Each observation of a comet's position gives two coordinates right ascension and declination, and hence to determine the five elements three complete observations are necessary Obviously it would be exceedingly difficult to tell the exact curve in which the comet is moving from a very small section of its orbit and when it is remembered that the center of a comet has nothing well defined about it and is difficult to measure it is not surprising that two preliminary orbits calculated by different persons from different observations perhaps, will disagree quite a little



After the elements are known it is possible to calculate the right ascension and declination which the comet will have at dates in the future A comparison of the calculated places and those observed will give a means of estimating the accuracy of the cometary orbit

Ordinarily the three observations used by the calculator for the comet's elements are those first published, which generally come on successive nights



A cablegram from Prof Kobold of Kiel, Germany, to Prof Pickering of Harvard College and by the latter distributed to American astronomers, gave the information that Kobold had computed an ephemeris for Beljgawsky's comet from observations made September 30th, October 1st and 3rd The elements were

Time of perihelion passage T = 1911 Oct 10. d 26 G M T.

Perihelion minus node	ω = 71 deg 39 min
Longitude of node	Ω = 88 deg 44 min
Inclination	i = 96 deg 38 min.
Perihelion distance	q = 0.0304

Brooks's comet September 22nd, 1911. Photographed with 10-inch Bruce telescope.

Beljgawsky's comet September 30th, 1911. Photographed with 10-inch Bruce telescope.

The ephemeris for Greenwich midnight follows

		RIGHT ASCENSION	DECLINATION.
1911	Oct 5	12 hrs 1 min 39 sec.	+12 deg. 11 min.
	9	12 hrs 57 min 53 sec	11 deg. 38 min.
	13	13 hrs. 50 min 4 sec	7 deg 45 min.
	17	14 hrs 30 min. 30 sec.	2 deg 16 min

A glance at the above elements at once showed to the expert astronomer that this was a most unusual comet Here was a comet moving almost at right angles to the plane of the ecliptic, and remarkable for that reason The unit for measuring distances to comets is the distance from the earth to sun, and here was a comet coming within 3,000,000 miles of the sun This insured that the comet would be a brilliant one, but the perihelion passage occurring on October 10th told that the comet would soon dwindle in brilliancy The right ascensions and declinations of the comet showed that it was moving south and east and since the comet was visible before sunrise, this meant that it would become invisible in the glare of the sun, to be seen later in the west after sunset On October 17th, Beljgawsky's comet set at 7 o'clock, and may be now seen shortly after sunset at the position given on the diagram above. The comet is now but a shadow of its former self.

The photograph shown is one by Prof Barnard on September 30th at 4 34 A. M with an exposure of only five minutes The tail was 5 or 6 degrees long to the naked eye, but the exposure had to be cut short on account of the approaching dawn On October 4th, another photograph by Prof Barnard shows a tail of about 8 degrees, slightly curved The convex side was toward the north with a streamer extending southward at an angle of 60 degrees with the main tail Considerable structure showed in the main tail and it had a shredded appearance On the next morning the sky was very hazy and Prof Barnard could see only the nucleus The original of the photograph of September 30th here reproduced shows much detail about the comet's head with a system of many streamers which go out from the head and give the tail a fan shape On this same morning, cometa Brooks and Beljgawsky could be seen at the same time with the naked eye—the former in the northeast near the handle of the Dipper, and the latter in the east near the horizon

Brooks's Comet.

Brooks's has been a most interesting comet because it has remained visible for so long to the naked eye On October 21st, this comet rise, at four o'clock about 20 degrees north of east, and rises about the same time for the week following, but each morning more nearly east Brooks's comet may be found from the diagram in the constellation of the Virgin It will be seen from this diagram that the paths of Beljgawsky's and Brooks's comets cross each other, but at the present time, the former is visible in the evening sky, east of the sun, the latter in the morning sky, west of the sun. The exquisite photograph of Brooks's comet by Prof Barnard, reproduced here, was made at 9 10 P M., September 22nd, with an exposure of three hours and a half, and shows a tail for about 9 degrees. The trails of light on the photograph are the stars which become elongated to lines of ligh, as the comet moved with respect to the stars while the photograph was being taken The comet was followed closely for the 3 hours 30 minutes necessary to make the exposure by keeping the eye constantly at the eye end of the telescope attached to the camera for guiding purposes

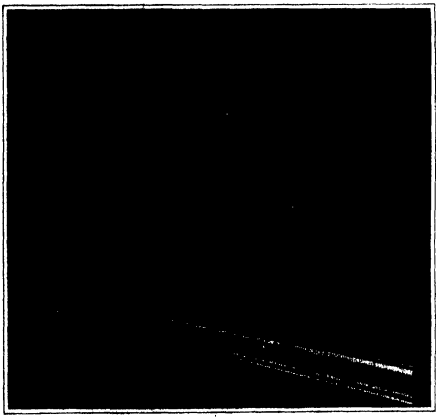
The diagram of Brooks's comet shows that it was picked up about as soon as it possibly could be. The diagram also shows that in November the comet will be moving directly away from the earth and will dwindle in brightness very quickly

Quenisset Comet.

This comet is fainter than the other two, and has suffered in consequence. It was discovered 15 degrees from the North Pole. On October 19th It was in the middle of the Northern Crown It passes almost due south about a degree a day from the Northern Crown into the Serpent. It is very slowly increasing in brightness.

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them



Freaks in Art and Their Scientific Explanation

THE grotesque has always had its place in art. Probably the commonest example of the artist's indulgence in peculiar vagaries of his creative fancy, are the gargoyles which adorn certain portions of Gothic structures. Some logical justification for the introduction of these grotesque figures is derived from the symbolical significance attached to them. Now and again in a work of art is found a similar element of freak, though it is not always easy, in such cases, to divine the author's reasons for resorting to such peculiar eccentricity. Two famous instances of this kind are figured in our illustrations, reproduced from the *Illustrated London News*. The first of these is a copy of Holbein's "Ambassadors," in the foreground of which, apparently without relevance of any kind, appears a skull, distorted almost out of recognition, its outline being roughly fish-shaped. There has been a good deal of discussion as to the significance of this picture. The explanation which bears the greatest semblance of probability is one given by Miss Mary F. S. Hervey, according to which the two personages appearing on the painting are identified as Jean de Dinteville, Ambassador from France to England in 1533, and his friend Georges de Selve. A recent discovery has placed beyond question the correctness of Miss Hervey's conjecture. A companion picture to the one here reproduced has been discovered, on which the same Jean de Dinteville appears, his name being worked into the hem of his garment. The evidence is such as to fully establish the identity of the Ambassador. As regards the mysterious skull in the foreground, Miss Hervey tells us that Dinteville had become acquainted in England with Holbein's "Dance of Death" series, and had adopted the skull as his personal badge.

Holbein's "Ambassadors" with the mysterious skull in the foreground

Our second illustration shows a view of an extraordinary portrait of Edward VI. This portrait is so distorted that it presents a normal appearance only when viewed through an aperture in a screen attached to the side of the frame. The painting is described in the catalogue of the National Portrait Gallery as "Edward VI; King 1537-1553, Painting in Perspective, 1546, by a French Artist." It is difficult to imagine what motive the painter might have had in choosing this strange method of presentation, unless it was purely a desire to do something unusual.

The "Painting in Perspective" of Edward VI.

Man's Fossil Remains

DR. W. D. MATTHEW, Curator of the American Museum of Natural History, has given the following information to the editor of the New York *Times* in answer to a curious correspondent, who asked "How do scientists account for the fact that so very few fossil human bones are found, while those of animals, that seem to have lived in the same period, are plentiful?"

"Human remains," says Dr. Matthew, "are found only in the latest geological formations. No authenticated remains are older than the Pleistocene epoch (ice age). In North America they are all very late Pleistocene. They are not especially rare as compared with the remains of lower animals, but most of the finds are due to interments of one kind or another.

"In the older formations (Tertiary and preceding periods) the bones of extinct animals are found, sometimes in abundance, but no remains certainly attributable to man or to any direct ancestor of man have been found. All reports to the contrary are based on questionable or insufficient evidence. These facts are true of the regions which have been extensively explored for fossil remains, viz., the greater part of Europe, a large part of the United States, and minor areas in other parts of the world.

"The obvious inferences are that man probably did not inhabit those parts of the world until during or after the great ice age, that he did not evolve from lower animals in these regions, and that the practice of interring the dead, instead of leaving them at the mercy of wild beasts, was a very ancient and universal custom among primitive races of man.

"The regions explored are a small fraction—possibly five per cent—of the area of Tertiary formations of the same nature known or believed to exist in different parts of the world. There are vast areas of promising "badlands" in every continent, which have been little or not at all searched by fossil hunters (these specimens are very rarely noticed or recognized by others). Even in the Western States, fifty years of exploration are so far from exhausting the field that every summer some expedition reports finding extinct animals hitherto unknown to science. Nevertheless we know enough to make it very improbable that the ancestry of man will be found in the Tertiary of North America. There is a great deal of indirect evidence, in the present distribution of the races of mankind, and what is known of the history of their migration, and from other sources, all pointing toward Asia, and especially Central Asia, as the original home of the race and the theater of its evolution during the Tertiary period. This is unexplored territory to the paleontologist, and too difficult and dangerous for systematic search even to-day. But if it is opened up to exploration during the next half century as the Western States have been in the past fifty years, we may look to find there the remains of Tertiary ancestors of man along with those of various lower races of animals which are believed to have originated in that region. If, after a thorough search, this belief is not substantiated, explanations will be in order, and it will be necessary for us to modify or reconsider our present views as to where and how man originated."

The Influence of Environment on the Composition of Wheat

THE variation in the composition of plants of the same species when grown under different conditions has been the subject of so much study during the past half century that a monograph published by the United States Department of Agriculture on the subject will undoubtedly be welcomed by students of physiological chemistry. The monograph in question was prepared by Mr. J. A. Le Clerc, with the collaboration of Sherman Leavitt, and is entitled "Tri-Local Experiments on the Composition of Wheat."

The experiments recorded were begun in 1905 with the collaboration of the Office of Grain Investigations of the Bureau of Plant Industry, and consisted in growing wheat from the same original seed continuously in each of the three apices of a triangle, for example (1) in Kansas, Texas and California, (2) in South Dakota, Kansas and California. The crop from each apex was then sent to the other two stations and there grown under the same conditions as the continuously grown seed. There were thus three plots at each apex or station all from the same original seed, one plot grown continuously at that point, the seed of the other two plots coming from the other points of the triangle. By this interchange of seed it was possible to determine the influence of climate and soil and of the kind of seed on the composition of the crop.

From the data obtained the following conclusions may be drawn:

Wheat of the same variety obtained from different sources and possessing widely different chemical and physical characteristics, when grown side by side in one locality, yields crops which are almost the same in appearance and in composition. Wheat of any one variety, from any one source and absolutely alike in chemical and physical characteristics, when grown in different localities possessing different climatic conditions, yields crops of very widely different appearance and very different in chemical composition. These differences are due for the most part to climatic conditions prevailing at the time of growth. The results so far obtained would seem to indicate that the soil and seed play a relatively small part in influencing the composition of crops.

The practice of trying to improve crops in one locality, which crops are to be grown in another locality of widely different climatic conditions, should be discouraged. Crops should be improved in the locality in which they are intended to be grown, or the seed should be selected from a region which has similar climatic conditions.

Rodgers's Flight Across the Continent

AVIATOR C. P. Rodgers reached Chicago at noon on Sunday, the 8th inst. He covered the 26 miles from Hammond, Ind., in 24 minutes, after a delay of two days at the latter place on account of inclement weather. His total flying time for the 1,199 miles was 21 hours and 53 minutes. During the next three days Rodgers succeeded in reaching Kansas City, 1,483 miles from New York, and about half-way across the continent.

Relative Strength of the Italian and Turkish Navies

A Comparison of Fleets Ancient and Modern

EVERY naval conflict, no matter how insignificant, or how great the disparity between the rival fleets, should furnish its quota of that technical information, upon which the designs of fighting ships are based and by which changes in the strategy and tactics of the future are modified. Those of us who have followed modern naval history with any close attention will call to mind the historic fight between Chilian and Peruvian armored ships, and the value which was placed upon the technical results of that struggle.

The principal object lesson of the present war between Italy and Turkey is that of the great value of the command of the sea. War had not been declared many hours before the Turkish government found itself as absolutely separated from Tripoli, the cause of contention, as though that place were located upon the planet Mars instead of upon the opposite shores of the Mediterranean Sea.

The situation will turn the minds of all thoughtful Americans to the far-distant Philippines, Hawaii, and the Panama Canal, and the question will be asked: "Is not four, rather than two battleships a year the correct standard, if we are to hold these distant possessions beyond all possibility of loss?"

Granting that in the strength of their land forces the Italian and Turkish nations are fairly well matched, it is evident at a glance that the disparity in the naval forces is so great as to render the present contest on the high seas almost farcical. If the Turkish navy should give a good account of itself, it will certainly not be because of its strength in ships, guns and men. With few exceptions, all the ships Turkey possesses were obsolete before the keels of the modern fleets of the nations were laid.

The Turkish fleet consist of three battleships, the "Hairredin Barbarosse," the "Torgud Reis" and the "Messudiyeh." The first two are castoffs of the German navy, which were built twenty years ago and were unloaded on Turkey last year. They were formerly the Friedrich Wilhelm and the Wiessenburg, and they carry, each, six 11-inch guns of an old pattern, in three center-line turrets. The armor is of the old compound type and the original speed of the ships was 17 knots. The third battleship, the "Messudiyeh," built in 1874, reconstructed in 1902, is of 10,000 tons displacement, 16 knots speed, and is armored with two 9 2-inch guns and twelve 6-inch, and protected with 12-inch iron armor. These three battleships combined would be no match for any one of the modern Italian battleships.

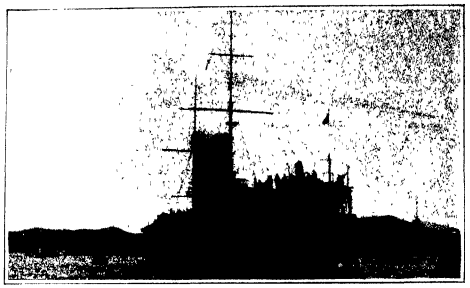
In the protected cruiser class, Turkey possesses three modern vessels, the "Hamidieh" and a sister ship, both of which were built in Europe. They are of 3,800 tons, and 22 knots speed, and carry two 6-inch and eight 4.7-inch guns. Another modern vessel is the "Medjidieh," of 3,320 tons, built by the Cramps, in 1904. This is also a 22-knot vessel, carrying two 6-inch and eight 4.7-inch guns. All three of these cruisers rely for protection on a 4-inch protective deck.

The rest of the fleet is made up of four obsolete vessels, of 2,400 to 5,000 tons displacement and 12 knots design speed, built in the 60's, carrying iron armor and four 6-inch guns, which are to-day of practically no value. Two 775 ton gunboats, built in 1906, a 500 ton gunboat built in 1907, one of 775 tons built in 1890 and seven of 213 tons and 12-knot speed, built in 1907-09, with eight other gunboats of 200 to 600 tons, and 12-knot speed, complete the list of larger vessels of the Turkish navy.

In destroyers Turkey possesses some modern vessels, including four of 620 tons and over 30 knots, and four of 305 tons and 28 knots. The navy includes also fourteen torpedo boats, built between 1901 and 1907, of 26 to 27 knots speed.

From the above enumeration it will be seen that the Turkish navy is incapable of fighting a fleet action with a modern navy. Her fast cruisers, in the hands of skilfull and daring officers, might prove effective in damaging Italian commerce or threatening the line of Italian communications, although Italy's fast cruisers should be able to capture and destroy these vessels or drive them under the shelter of Turkish land fortifications.

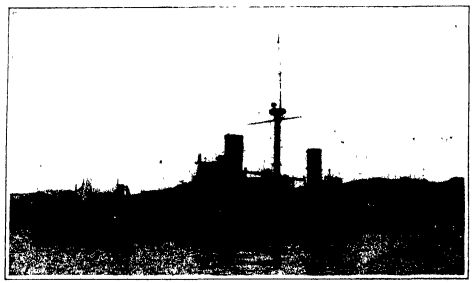
The Italian navy is worthy of a maritime people who have contributed largely to the development of the modern types of war ships. The battleships in particular are noted for carrying unusually heavy armaments and possessing speeds that are higher than the average of other navies. The most important vessels are three of the "Conti di Cavour" class, 21,500 tons and 22.5 knots, which are the first battleships to carry thirteen 12-inch guns, nine of them in three 3-gun turrets and four in two 2-gun turrets, all on the center line. Practically completed is another fine ship, the "Dante Alighieri," 19,000 tons, 23 knots, which will carry twelve 12-inch in four 3-gun center line turrets.



Of pre-dreadnoughts the Italian navy possesses four of the "Vittorio Emanuele" class (1904-7), viz., the "Emanuele," "Regina Elena," "Napoli" and "Roma"; 12,625 tons, 21 knots, carrying in turrets two 12-inch and twelve 8-inch, and protected by a 10-inch belt of Terni face-hardened armor. The "Benedetto Brin" and "Regina Margherita" (1901), of 13,427 tons and 202 knots are heavily armed, but lightly protected battleships, mounting in turrets four 12's, four 8's and twelve 6's, and protected by a belt of only 6-inch maximum thickness. The "San Giorgio" and "San Marco" (1908), of 9,830 tons and 23 knots, carry four 10's and eight 7.5's, all in two-gun turrets. They are protected by an 8-inch belt. The "Pisa" and "Amalfi" (1907-8), of 10,118 tons, 23 knots, carry the same armament and belt.

In armored vessels the Italians also possess five armored cruisers, of 7,400 to 9,800 tons (1897-1902), which are of the same general class as the "Cristobal Colon," of the Spanish war, and the "Kasuga" of the Japanese navy. These are the "Garibaldi," "Varese" and "Francesco Ferruccio," of 7,400 tons and 20 knot speed, protected by a 6-inch belt, carrying one 10-inch gun and two 8-inch in turrets and a broadside of fourteen 6-inch. The other two are the "St. Bon" and "Filiberto," 9,800 tons, 18 knots speed, 9¾-inch belt, carrying four 10-inch in turrets and eight 6-inch and eight 4.7-inch guns in broadside. The "Carlo Alberto" and "Vettor Pisani" (1895-96), 6,500 tons and 19 knots, are protected by a 6-inch belt and mount twelve 6-inch and six 4.7-inch in broadside. The "Marco Polo" (1892), 4,583 tons, 19 knots, protected by a 4-inch belt and mounting six 6-inch and four 4.7 inch, dates from 1892.

The above completes the list of modern armored vessels of the Italian navy, and the fact will be recognized that the ships are generally of first-class design.

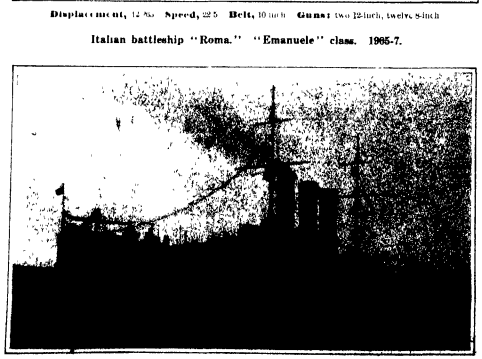


Of old armored vessels Italy possesses the "Sicilia," the "Re Umberto" and "Sardegla" (1887-91), of 13,500 tons and about 18 knots speed, armed with old 13.5 and 6-inch guns, and protected by a 4½-inch belt. Then there are the "Dandolo," "Italia" and the "Lepanto." The first-named was built in 1878, and mounts four 10-inch, seven 6-inch and five 4.7 inch guns. The "Italia" and "Lepanto," of about 15,500 tons, built in 1880-83, were phenomenal ships of their day, since they had no belt armor and yet mounted four 17-inch 100-ton guns. They were originally built for 18 knots.

(Continued on page 877.)

Displacement, 12,625 tons. Speed, 22.5 knots. Belt, 9 inch. Guns, two 12-inch, twelve 8-inch.

Italian battleship "Regina Elena." "Emanuele" class. 1905-7.

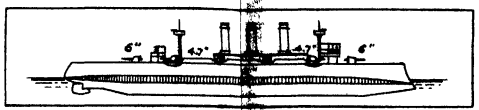


Displacement, 9,800 tons. Speed, 18.4. Belt, 9¾ inch. Guns: four 10-inch, eight 6-inch, eight 4.7-inch.

Italian battleship "St. Bon." Also "Filiberto." 1897.

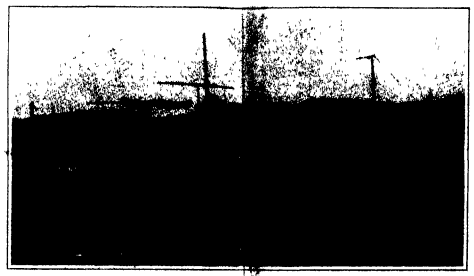
Displacement, 12,625 tons. Speed, 22.5. Belt, 10 inch. Guns: two 12-inch, twelve, 8-inch.

Italian battleship "Roma." "Emanuele" class. 1905-7.



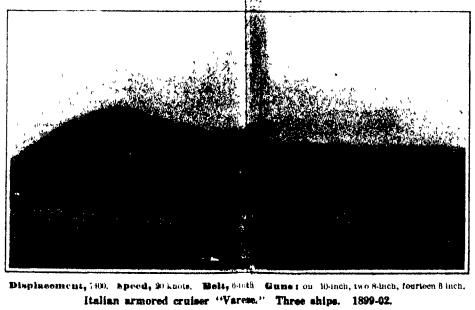
Displacement, 13,427 tons. Speed, 22.5 knots. Belt, 10 inch. Guns: two 12-inch, twelve 8-inch.

Italian battleship "Vittorio Emanuele." Four ships. 1904-7.



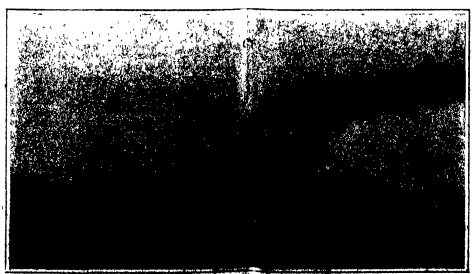
Displacement, 10,000 tons. Speed, 17 knots. Belt, [illegible]. Guns: six 11-inch; eight 4-inch. Date, 1891.

Turkish battleship "Torgud Reis." Also "H. Barbarosse."



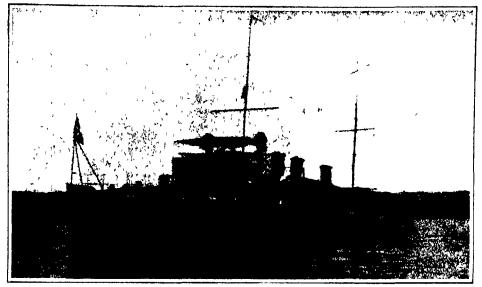
Displacement, 3800 tons. Speed, 22 knots. Deck, [illegible]. Guns: two 6-inch, eight 4.7 inch. Date, 1903.

Turkish cruiser "Hamidieh." Class of three ships.



Displacement, 160 tons. Speed: surface 11 knots, submerged 9 knots. Two torpedo tubes.

Italian submarine "Narvalo." Five vessels. 1903-6.

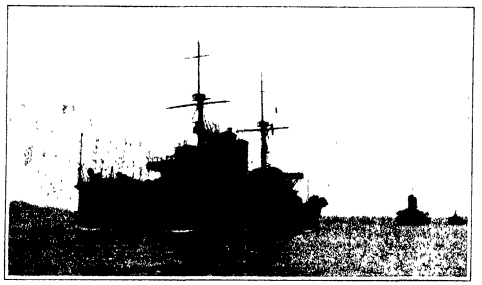


Displacement, 7900. Speed, 20 knots. Belt, 6-inch. Guns: one 10-inch, two 8-inch, fourteen 6 inch.

Italian armored cruiser "Varese." Three ships. 1899-02.

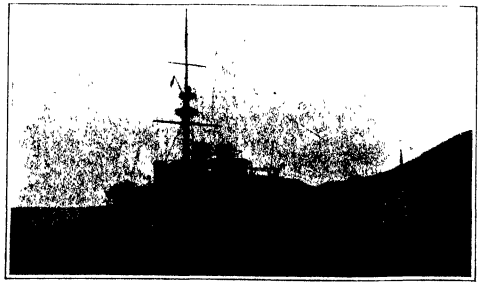
Displacement, 10,118 tons. Speed, 23.6 knots. Belt, 6-inch. Guns: four 10-inch, eight 7.5-inch.

Italian battleship "Amalfi" [illegible] "Pisa." 1907-8.



Displacement, 240 tons. Speed, 28.5. Torpedo tubes, three. Guns, four 4-inch.

Italian destroyer "Bersaglieri." Ten boats. 1907-10.



Displacement, 6300 tons. Speed, 19 knots. Belt, 6-inch. Guns, twelve 6-inch, six 4.7-inch.

Italian armored cruiser "Pisani." Also "Alberta." 1895.

Displacement, 13,427 tons. Speed, 20.2 knots. Belt, 6-inch. Guns, four 12-inch, four 8-inch, twelve 6-inch.

Italian battleship "Regina Margherita." Also "Benedetto Brin." 1901.

Displacement, 13,351 tons. Speed, 18 knots. Belt, 4½ inch. Guns, four 13.5 inch, eight 6-inch, sixteen 4.7 inch.

Italian battleship "Re Umberto." Three ships. 1887-91.

Small Isolated Electric Power Plants

Some Practical Suggestions on Building Them

By Frederick E. Ward

EVER since the invention of the incandescent lamp, and its resulting widespread adoption for the lighting of dwellings, many persons living outside the zones supplied with current by central stations have desired to possess small lighting plants of their own. Heretofore, however, this has not been practical for the man of moderate means, because of the large amount of power consumed by the carbon-filament lamp and the necessarily large outlay for equipment and running expenses.

Recent progress in the lampmaker's art has resulted in giving us the tungsten filament, which is three times as economical in the consumption of power as the old carbon lamp, so that now an ordinary sized dwelling can be brilliantly lighted by so simple and inexpensive an outfit as would seem to place this with *in the reach of a* great many who cannot get electricity from central stations.

The following description will give first a good idea of a suitable plant for the practical lighting of a house wired for a total of about eighteen sixteen candle-power lamps. As all the lamps located in the various parts of a house are not required to be lighted at the same time, it is assumed that ordinarily not over seven lamps will be used, and that the maximum demand on special occasions such as receptions or parties, will be for twelve lamps to burn all night.

In cases where a plant is to be installed principally for lighting, and it is not intended to operate electric heating devices or motors, except in small sizes and only occasionally, then thirty-two volts is probably the best selection that can be made for the system. This has been adopted as a standard voltage for the lighting of railroad cars, and tungsten lampmakers are prepared to furnish lamps for it in candle-power of 8, 12 and 16.

The necessary equipment of a plant consists of four parts, the engine, the generator, the switchboard and the storage battery. In general it is best to buy these from manufacturers who make a specialty of such apparatus, but the Handy Man who can spare the time can no doubt derive much pleasure from making a large part of the apparatus himself, as hereinafter more particularly described.

An electric lighting outfit takes up but little room and may be installed in one corner of the tool-house, garage or other outbuilding if one does not wish to erect a separate house for it. In the photograph in Fig. 1, is shown a neat power-house of field stone built over a live spring at the foot of a hill. The same engine that runs the dynamo also drives a lathe and grindstone, as well as running a pump supplying the house tank with water from the spring.

The simplest and most economical form of storage battery to buy is known as the two-plate, or couple type, which consists of two plates in each jar, supported by hard connecting straps resting across the edges of the adjacent jars. Sixteen cells are required for a thirty-two volt system, and these, having a capacity of thirty-six ampere-hours, can be purchased for about fifty-five dollars.

Sometimes a bargain can be found in the way of a battery, suitable for a very small plant in the second hand or discarded electric vehicle battery of the lead type. Cells of this kind, when new, have a capacity of about 120 ampere-hours, but this is soon reduced by the severe conditions of service, and when the point is reached where the vehicle will no longer run a sufficient number of miles on a charge the battery plates have to be replaced by new ones. The old plates, which go back to the melting pot, usually can be purchased for very little money, and, when properly cleaned and assembled in suitable glass jars, will give many months of useful service.

For those who prefer to make their own batteries, however, some good hints were given in this department of the SCIENTIFIC AMERICAN of March 11th, 1911. A simpler form of construction has been devised by the author, embodying the modifications shown in the upper left-hand corner of Fig. 2, where the positive and negative elements are separated by a porous earthen flower-pot instead of by strips of wood. This construction has the advantage of a considerable saving in labor, as the lead cylinders do not have to be nicely made or riveted, and of an increase in useful life as short-circuits cannot be formed by active material falling to the bottom of the jar between the plates.

As the capacity of a cell of this kind is not directly proportional to its weight, it is more desirable to make thirty-two small cells than sixteen larger ones. The small cells can be connected in two series of sixteen each, thus becoming equivalent to sixteen cells of double the size. For those who have had little or no previous experience in this kind of work it is recommended that only one-half of the batteries be made to start with, and that the second half be attempted only after the first series have been put in service long enough to show up possible defects.

For a cell of suitable capacity, the containing vessel may be a glass jar or a glazed earthen crock having inside dimensions not less than 5½ inches diameter by 5½ inches high. The flower-pot may be 4½ inches outside diameter at the top by 4¼ inches high. Plug up the hole in the bottom by standing the pot on a sheet of paper and pouring in just enough melted sealing wax to fill the hole, but not to cover the bottom.

In assembling, put a thin layer of the granulated lead in the bottom of the crock *J*, and pack it down well. Stand the flower-pot *P* in the middle, and bend one strip of 1/16 inch sheet lead *E* to fit inside the pot and one to fit outside. These "cylinders" may be

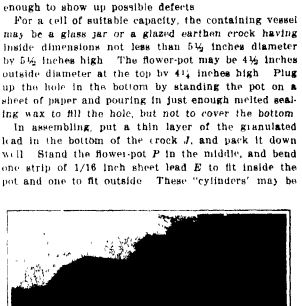


Fig. 1.—A small power house.

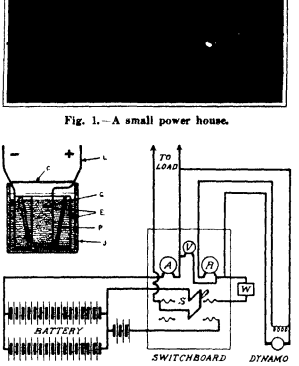

Fig. 2.—Details of storage cell and diagram of connections.

the same height as the pot, and the terminal straps *L* may be formed by bending up strips one inch wide partly cut from the metal, thus doing away with riveted connectors. Pack the remaining spaces in the crock and the pot with granulated lead *G*, up to within a quarter of an inch of the rim of the pot. It is very important to arrange the connecting straps *L* so that they may be bent to pass out at diametrically opposite points close to the rim of the crock, so as to leave room between them to lay a square of glass *C* to serve as a cover. These covers are necessary to catch the fine spray of acid that would otherwise fly out during charging.

A cell of the dimensions given requires a total of about seven pounds of lead, of which about 4¾ pounds are granulated. Granulated lead is prepared by heating melted lead red hot in the ladle and then pouring it from a height of about five feet into a pail of water. In storage battery work success depends largely on the use of pure materials. In selecting the lead for granulating reject anything suspected of containing solder, zinc or other impurities. Never use the cheap, or "commercial" sulphuric acid, or water that is "hard." Use a good quality of acid and either distilled or rain water.

The proper electrolyte to use in the cells is dilute sulphuric acid of a specific gravity of 1.2. This can be purchased already prepared, or it can be made by slowly adding one part of concentrated acid to each five parts of water. When the cells are filled to a point one-quarter of an inch above the flower-pots, the level of the liquid should be nearly an inch below the tops of the crocks.

The completed cells should be arranged in shallow wooden trays, the bottoms of which are covered with a layer of clean sand about half an inch deep. Not more than eight cells should be grouped in a single tray, on account of leakage of current over the surface of the jars and through the sand. After the jars are in place, the surface of the sand all around them may be liberally dusted with dry sodium bicarbonate (baking soda) which not only neutralizes any acid that slops over on the sand, but tends to keep the last dry, as the sodium sulphate formed is an efflorescent salt.

It is well to remember that a solution of bicarbonate of soda in water is the best wash for use in the event of any acid getting spattered in one's eyes, and the author recommends that a bottle of this be kept in a handy place for use in such an emergency.

Thirty-two of the cells made as described will cost less than twenty-five dollars for the materials alone, but to this must be added the cost of current used in the forming process, which takes considerable time.

To form the cells properly a current of three or four amperes should be passed through each series of them, either continuously or intermittently for a total of about fifty hours. Then they should be completely discharged and reversed, or given a similar charge in the opposite direction. About ten such reversals are required to develop sufficient capacity for practical purposes. When this has been accomplished always charge the cells in the direction that makes the central plate positive.

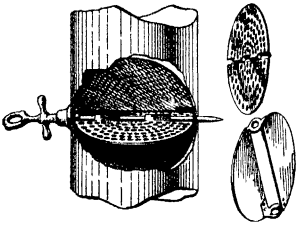
For charging the battery a shunt-wound generator, or dynamo, is required. For those who may care to build this part of the apparatus, the design given in SCIENTIFIC AMERICAN SUPPLEMENT, No. 600, is to be commended on account of its very complete description. A machine built in accordance with those instructions may be made to serve a useful purpose, especially if it be provided with more modern ring-oiling bearings and carbon brushes, to insure against the need of shutting down for hot boxes and commutator troubles. A more modern and dependable generator, however, can be purchased for about twenty-five dollars. In ordering a machine it should be required to meet the following specifications: Volts, 42; amperes, 5; speed, 1,800 to 2,000 revolutions per minute; type, shunt generator.

The most satisfactory kind of power to use for driving the generator is the small gasoline engine. One-half horse-power would be ample for this purpose, but as yet few engine makers have developed anything in so small a size, so that good, reliable engines are to be had only in sizes beginning with about one horse-power, and costing from thirty dollars upward. Where there is water power available even less than one-half horse-power will give good results, since the water-wheel requires no attention and may be allowed to charge the battery slowly and for long periods of time.

Where one already has any kind of power at hand it may not be necessary to buy an engine to run the generator. For wherever there is a steam engine, gasoline engine or a water-wheel already installed for doing other work, a suitable pulley and belt may be arranged to drive the generator, and the power thus absorbed will be so small that in many cases it never will be missed.

A simple and convenient arrangement of the switchboard connections is also shown in Fig. 2. It is necessary to have an ammeter *A* to measure the current passing through the battery. The most desirable scale is one having the zero in the middle and reading up to ten amperes on each side, showing charge or discharge. A voltmeter *V* is also a great convenience, but is not essential, as the working of the generator can be indicated by a 4 candle-power 16-volt lamp.

In order to charge the storage battery, the dynamo must impress upon the battery's terminals a voltage considerably higher than thirty-two. This means that if any lamps are lighted while the charging is being done they will take so much current at the increased pressure as to be quickly burned out. To guard against this mishap there are shown in the diagram three extra cells of battery in addition to those previously mentioned. These extra cells are called c. e. m. f. (counter electro-motive force) cells, and their purpose is to oppose or neutralize about one-fifth of the pressure that would otherwise be applied to the lamp. The c. e. m. f. cells may be more easily made than the

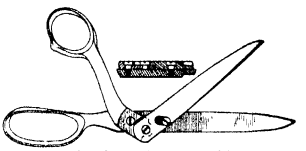


(Continued on page 378.)

The Inventor's Department

Simple Patent Law; Patent Office News; Inventions New and Interesting

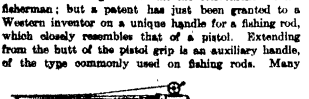
Oddities in Inventions



Safety Spark and Draft Damper.—Threatened with a fire in his own home by sparks passing up through the stove pipe into the chimney and alighting on the shingle roof, an inventor recently designed the damper illustrated in the accompanying photograph. It consists of two parts, one f which is the damper proper and the other the spark arrester. The spark arrester has a perforated disk which along the center line is stamped to form a square socket or a spindle. Mounted on this spindle is a handle that operates the draft damper. In use, the spark arrester normally lies crosswise in the stove pipe and the draft damper may be operated at

Combined spark arrester and draft damper.

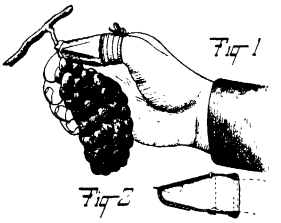
will by turning the handle on the sleeve. A perforated plate prevents the sparks from passing up through the chimney and it also collects soot which would otherwise clog the chimney. Whenever it is desired to clear the plate of soot, the spindle may be turned, causing the spark arrester disk to strike against th draft damper and thus shake off the soot.



Shears With Compound Leverage.—Scissors or shears as ordinarily constructed r present the simplest type of leverage. Two inventors living in Oregon have sought to improve on this by producing a compound leverage, at the same time the blades are so arranged as to afford a draw cut, thereby improving the efficiency of the device, particularly when cutting heavy materials. As will be noted in our illustration, one of the blades is

Draw-cutting shears with compound leverage.

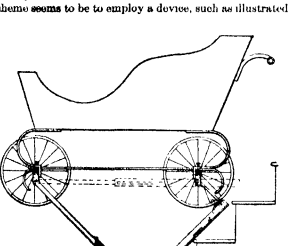
integral with the handle, while the other blade is fulcrumed on a screw in the first blade and is hinged to the short arm of a lever that constitutes the other handle. The fulcrum of the blade jus referred to is not fixed; instead, the blade is slo te so that it is movable endwise upon its fulcrum, to oo pensate for the arc of travel of the short arm of the handle lever. When the handles are brought together there is a toggle action on this blade, while its movement upon its fulcrum produces the desired draw cut.



Pistol Handles for Fishing Rods.—Heretofore no particular care has been exercised in designing the handle of a fishing rod to suit the convenience of the fisherman; but a patent has just been granted to a Western inventor on a unique handle for a fishing rod, which closely resembles that of a pistol. Extending from the butt of the pistol grip is an auxiliary handle, of the type commonly used on fishing rods. Many

Fishing rod with pistol grip.

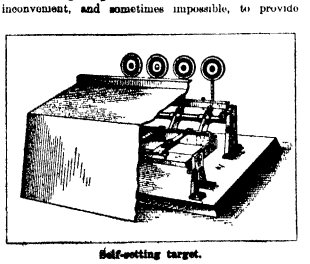
advantages are claimed for this double form of handle. The fisherman in ordinary still fishing may support the auxiliary handle under his forearm while grasping the pistol grip in his hand. This will give him a much better leverage for handling a fish, and will be less tiring.



Thumb Knife for Picking Fruit.—A very convenient device for picking fruit has been designed by a man living in the fruit regions of California. It consists of a thimble, which may be tied to the thumb and which terminates in a blade with a keen edge. The fruit is seized in the hand and the stem is severed by means of

Picking fruit with a thumb knife.

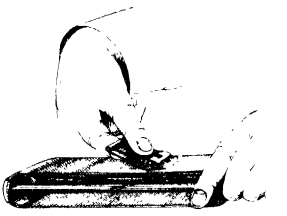
the thumb knife. With such a device as this the picking of fruit is materially expedited and there is no danger of tearing the branches or marring the fruit when it is plucked.



Stairway Skids for Baby Carriages.—It is always a precarious task to take a baby carriage, step by step, down a stairway. Not infrequently the handle gives way and the carriage is dashed to the bottom. Furthermore, the jar of bumping down the steps cannot be entirely avoided, and is injurious to the child. A better scheme seems to be to employ a device, such as illustrated

Up and down steps on skids.

herewith, which consists in a pair of skids that slide smoothly down the steps. The skids are permanently secured to the carriage and normally occupy the position indicated by dotted lines. When it is desired to use them, they are adjusted to the position shown in full lines. The skids are held in this position by bars attached to the front axle, which have sliding connection with the skids and hence, under normal condition, may be telescoped with them.



Self-setting Target.—Under certain conditions it is inconvenient, and sometimes impossible, to provide

Self-setting target.

manually operated target resetting devices, particularly for long ranges. In such circumstances, the self-setting target here illustrated should prove of value. The targets, which may be of any number desired, are mounted on bell-crank levers, weighted to keep them upright. When a target is struck by a bullet, the lever is swung on its axis, and the toe of the weighted arm snaps past a leaf spring, which serves to retain the target in depressed position. Target after target may thus be depressed, but when the last of the set has been shot down, the entire series of targets is reset. The leaf springs which hold the individual targets are mounted on a frame which is normally held in horizontal position by a counterweight. The accumulated weight of the entire series of bell-crank levers is sufficient to overbalance this counterweight, causing the frame to swing on its axis and liberate the levers, which thereupon swing back to their normal position.

Razor-stropping Device.—The advent of the safety razor has made necessary the use of special forms of razor strops, particularly adapted for sharpening the short handleless razor blades. One of these razor stropping devices is illustrated herewith. The razor blade is gripped by a small carrier connected by a pair of

Razor-stropping device.

links to a frame around which the razor strop is stretched. Owing to the double link connection with the carrier, the razor blade is always maintained at the proper angle with respect to the strop, as it is moved along the leather. At the end of the stroke the two links serve to lift the blade clear of the strop, permitting it to be turned over to bring the opposite side to bear.

Ever-level Table for Ships.—Many different types of tables and chairs have been invented for use on ships in time of storm. As a rule they are designed on the pendulum principle and are arranged to swing relatively to the ship, under the action of gravity, thus maintaining a constant horizontal position. The objection to this scheme is that the table or chair is apt to sway, and is never perfectly steady. Seeking to overcome this difficulty, and inventor in Texas has designed the table pictured in the accompanying drawing. The table top is mounted on a ball joint, which is supported on four

Ever-level table.

legs secured to the deck or floor of the vessel. Extending from this ball joint is a rod supporting a heavy weight at its lower end. This is the pendulum that holds the table top level. However, in order to damp the oscillation of the pendulum, four oil cylinders are attached to the table legs, while the plungers that play in these cylinders are connected by ball joints to the pendulum rod. The cylinders are filled with oil and the plungers are provided with perforations, to permit the passage of the oil through them as they move in and out of the cylinders. The viscosity of the oil tends to make the pendulum move sluggishly, but not so sluggishly as to prevent the table from keeping its horizontal position as the ship rolls.

Notes for Inventors

Attitude of Patent Office Toward Perpetual Motion The Patent Office regards perpetual motion as meaning a mechanical motion which creates energy, that is to say a machine which works and operates without the aid of any power other than that generated by the machine itself and which machine, when once started, will operate for an indefinite time The Patent Office also holds that these views are in accord with those of the scientists who have investigated the subject and are to the effect that mechanical perpetual motion is a physical impossibility These views can be successfully rebutted only by the exhibition of a working model, and while many persons have filed applications for patents on perpetual motion, such applications have been rejected as being inoperative and as opposed to well-known physical laws and in no instance has the requirement of the Patent Office for a working model been complied with The Patent Office will not now permit an application for patent on perpetual motion to be filed without a model, this practice having been adopted by the Patent Office to save applicants for patent the loss of fees paid with their applications in cases where perpetual motion has been claimed After an application for patent has been considered by the Patent Office Examiner, the first government fee of $15 00 cannot be returned

Five Patents to a Montclair Inventor. Among the patents issued September 5th, 1911, are five patents, No 1,002,246 to No 1,002,249, and No 1,002,506, to Carleton Ellis of Montclair, N J., assignor to Ellis-Foster Company, for continuous process and apparatus for making white lead, Agricultural Spray Composition, Inoculated Humus and Process of Making Same, Electrical Oxidation of Nitrogen and Seasoning Material and Making Same

A Telephone Mouth-piece Improvement. Gustavus A Durvee of New York city has patented, No 1,002,248, a telephone attachment in which the mouth-piece is yieldingly supported in a casing, mounted upon the transmitter, so that the mouthpiece can adjust itself to the mouth of the speaker

A New Carwheel Molding Flask.—Alfred Cordingly of Denver, Colo., has secured a patent, No 1,003,709, for a carwheel molding flask with upper and lower sections, with upwardly projecting portions on the lower section which are bevoled to engage the upper section and maintain the sections in proper relation

A Safety Device for Flying Machines.—In patent No 1,003,711, to Josiah W Dalson of New York city, is shown a parachute having a lock for holding it normally collapsed and close to an aeroplane, together with means for automatically opening the parachute when the lock is released and for spreading the parachute when the lock is released the parachute being detachably connected to the aeroplane and having secured to it a take-off connection for supporting an aviator

High Speed Trolley Wheel. The patent, No 1,003,862, to Albert H Armstrong of Schenectady, N Y, assignor to the General Electric Company, presents a high speed trolley wheel which carries at its periphery and pendently pivoted blades which form freely movable contact making means that can be projected outwardly by centrifugal force to make contact with the trolley wire, irrespective of its varying distances from the axis of the wheel, and a motor is provided to positively rotate the trolley wheel

An Automobile Door Indicator.—Patent No 1,003,867, to Leon L Bories of San Francisco, Cal., provides for notifying a chauffeur when an automobile door is closed. This is done by providing a door actuated mechanism which serves, when the door is closed, to operate a suitable indicator

Paper as a Substitute for Laths—A novel plaster support for wall covering and forming a support for plaster, comprises a flexible, laminated sheet of paper board, capable of being compactly rolled and spaced, thin, flat strengthening strips extending transversely of and secured to one surface of the paper board This was patented, No 1,003,754, to Frederick L. Kane of Huntington, N. Y

A New Barber's Comb.—A hair-cutter's comb is shown in patent No. 1,003,588, to James L Woods of Cedar Rapids, Iowa It has teeth which gradually diminish in length from end to end of the comb, with one edge of the teeth formed with inclined portions and the remaining portion straight or parallel with the opposite edge of the teeth, so the comb can be utilized as a gage in cutting hair

Metal Railroad Ties.—Three patents, No 1,003,637 to No 1,003,639, have been granted to William Henry Morgan of Alliance, Ohio, for metal railroad ties, all three of the ties being characterized by cross or transverse portions and end portions which extend lengthwise the rails for supporting the latter

A Two-part Medicine Bottle.—A medicine bottle, having a bottle within it with the stopper of the inner bottle seated in the inner end of the stopper of the outer bottle, is shown in patent No 1,002,293, to Richard P McGrann of Lancaster, Pa

An Electrically Heated Hot Water Bag.—Patent No 1,002,253 presents a hot water bag having a removable stopper and an electrode carried by the stopper and exposed within the bag, the stopper having on its outer side special means for connection with an electric circuit, the electrode being removable with the stopper.

A Novel Lubricating Material.– Henry P White of Kalamazoo, Mich., presents in a patent, No 1,002,349, a packing material which includes crumpled sheet metal, coated with oil and powdered graphite and folded and compacted together

A New Mergenthaler Line Caster.–John R Rogers of Brooklyn, N Y, has assigned to the Mergenthaler Company a patent, No 1,002,320, for a line casting machine which has a magazine for use in an inclined position, which has a straight channeled body portion and a straight receiving end in alignment with the body portion and vertically partitioned

Detection of Counterfeits.—Patent No 1,002,900, to Edward Robert Morris and Alfred Edwin Bantree of London, England, provides for detecting counterfeits by applying to the fabric of the document distinctive identifying characters or designs and a ground work as specified, the characters and designs being discernible only by aid of a detector in the form of a special light

Two New Edison Patents – Thomas A Edison has in the *Gazette* of September 5th, 1911, two patents, one No 1,002,504, *for an apparatus for crushing* and separating fine materials, and the other, No 1,002 505, for a composition for sound records and other objects The latter is assigned to Thomas A Edison, Incorporated, and the composition includes shellac and a halogenized Naphthaline, crystallizing as fibers distributed through the shellac

An Allis-Chalmers Turbine.—Max Rotter of Milwaukee, Wis, has assigned to Allis-Chalmers Company, of the same place, a patent, No 1,002,813, for a turbine in which an exhaust pipe extends from an engine and is divided into two paths, one of which communicates with a condenser and the other path leads to the turbine, while a governor controls valves which limit the flow through the two paths

Wanted: An Automatic Doffer.—If someone could invent an efficient, satisfactory doffing machine for cotton spinning machines that would be automatic in its operation, it would doubtless quickly come into general use It should be applicable to the various styles of spinning frames and should not be limited in its usefulness to any particular style of bobbin, but should be capable of operating in connection with any of the different forms of bobbins met with in the modern spinning machine.

Legal Notes

"Collier" a Descriptive Term for Dynamite.—In the case of the Sinnamahoning Powder Manufacturing Company, the Patent Office has held that the word Collier, as applied to dynamite, is descriptive and not registrable, since it would indicate to the trade that it was intended for use in coal mining; also that the color of the package in which goods are placed cannot constitute a trade-mark for such goods, and that the Examiner of Trade-marks properly refused to allow the applicant to describe the mark as appearing on a red package

Acquiring Trade-mark Rights.—In acquiring the exclusive right to the use of a trade-mark, the important act is the actual use of the mark on the goods to which it applies, in commerce This, of course, includes the adoption of the mark, since it cannot be used until after its adoption, but the adoption alone of the mark, apart from a *bona fide* use thereof does not give any trade-mark rights therein. When once begun, the use of the mark must be continuous, since any cessation in the use tends to abandonment. The continuity of use depends on the goods; the market for some goods, fertilizers, seed corn and the like, has seasons of activity and seasons of quiet and the use of the mark follows the seasons.

Lecture on Trade-marks.—That the systematic study of trade-mark law is receiving more attention in the established schools of law, is evidenced by the announcement that this season Mr. William L Symons, the Assistant Examiner in the Trade-mark Division of the Patent Office, will deliver courses of lectures on the subject of Trade-marks, Prints and Labels and Unfair Competition in Trade, in the Washington College of Law, Washington, D C.; the Richmond College, School of Law at Richmond, Va., and the Washington and Lee University School of Law, at Lexington, Va

An Important Decision on Reissues.—In the U S Circuit Court of Appeals, Seventh Circuit, in Moneyweight Scale Company, the Court affirmed the decree below, sustaining the Reissue Patent, No 12,137 The Court said

"Authority to grant reissues is now derived exclusively from the statute (R S 4916, U S Comp St 1901, p 3383) And the Commissioner goes beyond his jurisdiction if he grants a reissue for an invention (though conceded to be the invention of the applicant) which is not the same invention that was disclosed and described as the applicant's invention by the original patent, which, by reason of inadvertence, accident, or mistake, is inoperative to secure the monopoly it shows on its face was intended to be secured"

Referring to the original patent, the Court says

"The two claims allowed do not fulfill the promise They are only for combinations of less than the total number of elements in the complete scale and are expressed in general terms The original patent on its face was therefore inoperative to protect the details of construction which the specification has particularly pointed out and which individualized the machine that appellee was manufacturing thereunder"

As to some of the claims presented during the prosecution of the original application, it is said

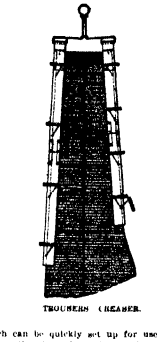
"We have examined each of the twenty-seven rejected claims and have failed to find one that would be adequate to secure a monopoly of the DeVilbiss computing scale, that would cover the details of construction in which the invention as an entirety resided."

The decision refers to the fact that none of the reissue claims corresponds with the subject matter of any abandoned claim; and that no reissue claim is broader than the allowed claims, and points out that—

"Where none of the original claims presented by an applicant for a patent was adequate to cover the invention disclosed by the specification and drawings, acquiescence in the rejection of such claims is not an abandonment of the invention as an entirety, and the failure of his solicitors to submit adequate claims is an inadvertence which may entitle the applicant to a reissue."

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.



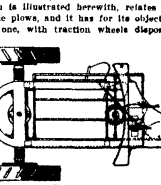
Pertaining to Apparel.

TREAD FOR BOOTS AND SHOES.—W. S. ACKER, Washington, D. C. The primary object of the inventor is to obviate many objectionable features and to present to the trade a heel or tread having a plurality of longitudinal wear resisting strips embedded therein so as to prevent slipping when walking on smooth or wet pavements, the invention being particularly adapted for use with cushion heels, as the strips do not impair the elastic or resilient properties thereof

REINFORCEMENT FOR GARMENT FORMS.—E. T. PALMENBERG, New York, N Y., and F W KRUESCH, Bayonne, N J. The object here is to provide a reinforcement for forms arranged to prevent cutting into the cloth covering of the form by the shears of the fitter, at the same time permitting the insertion of pins or similar fastening devices, generally used for holding the garment temporarily in place on the form during the fitting process.

SKIRT.—A. GOLDBERG, New York, N. Y. The aim of the improvement is to provide a simple and durable skirt, petticoat or the like, which can be easily put on and taken off, the waist band of which is adjustable so that the skirt can be worn by persons having different waist measurements, and which provides pockets for carrying valuables and the like

TROUSERS CREASER.—A. DOMBROWSKY, Las Cascadas, Panama. In this patent the invention is an improvement in trousers creasers and is fully shown in the side view illustration of the device as in use. The inventor's object is to provide a simple and novel construction which will be efficient in use, made in sections which can be conveniently detached to permit the device to be packed in small space and



TROUSERS CREASER.

which can be quickly set up for use By adjusting the clasp shown in the dotted line position at the bottom of the right hand side, it will operate to hold the side bars of the clamp firmly upon the trousers If desired, the clamps may be made one longer than the other to adapt them for use at the front and rear edges of the trousers leg as shown

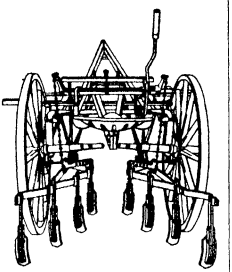
NECKTIE.—I LEWIS, New York, N Y This article is an improved form of reversible entirely woven necktie One of the objects of the invention is to provide an all-woven necktie which comes from the loom completely woven, having the neckband thereof the common tubular construction and the ends forming with the neckband a reversible open-ended four-in-hand tie

Of Interest to Farmers.

AUTOMOBILE PLOW.—OLIVER H LINCOLN and EDSON O PARKHURST, Brownell, Kan This invention, the sectional side view of which is illustrated herewith, relates to automobile plows, and it has for its object to provide one, with traction wheels disposed near

AUTOMOBILE PLOW.

the front and at all times in the same position relatively to the engine, whether the plow is being driven in a straight line or is being turned to one side or the other, the plowshares being disposed under the engine and



being held down to their work by the weight thereof. By a movement of a lever the plowshares may be moved up or down to a position where they will engage the earth and will do the general work desired, these plowshares being secured to the lower frame having the transverse members.

DEVICE FOR AERATING, COOLING, AND CLEANING MILK.—C. W. TICKNOR, Mount Kisco, N. Y. The intention in this case is to provide a conduit having ribs for collecting any dirt which may be in the milk, the conduit being cooled by an adjoining receptacle containing water, so that the milk will not only be cleaned, but will also be cooled and aerated when passing through the conduit

CULTIVATOR.—W. E. BROWN, Herrick, S. D. In this machine the operator has an easy and complete control. He can follow a row closely without covering or plowing up plants that may be on one side of the row. The disks may be guided to follow a row, regardless to a certain extent of the position of the supporting frame. In this movement both hands are left free for operating other parts of the machine, thus effecting the saving of time and the operator's strength.

MOTOR DISK PLOW.—J. M. HENTON, Edgemont, S. D. This invention provides a carrying frame and traction mechanism with means arranged to propel the frame intermittently and as controlled; provides means for, at will, varying the position of the driving wheels of the traction mechanism relatively to the grinding wheels of the frame to vary the pivot on which the frame is swung; provides rotary plowing members and a rotary driving mechanism arranged to rotate the plowing members independently of the traction mechanism of the carrying frame; provides devices for gripping the ground in a manner to form traction devices auxiliary to the main traction mechanism; and provides rotary plowing devices having means for shearing surface vegetation and shattering subsoil.

CULTIVATOR.—CLIFFORD A. CORWIN, P. O. Box 466, Riverhead, L. I., New York. The cultivator shown in rear perspective view in elevation, is of the adjustable type. The purpose of the inventor is to provide one with a series of hoes connected together so as to be adjusted simultaneously with means for locking them in an elevated position out of con-

CULTIVATOR.

tact with the ground, and with means for locking them in a plurality of adjusted positions intermediate their uppermost and lowermost positions. A plurality of hoes connected together is provided with means for taking up the shock incident to the change of position of the hoes. A cultivator with a plurality of wheels, forming a carriage to support the same, the wheels being adjustable relative to the frame so as to guide the cultivator

Of General Interest.

DISPLAY RACK.—T. N. FIGURES, JR., Columbia, Tenn. This rack is for use in shops or stores for displaying dry goods, gents' furnishings, or other articles. The same is preferably constructed and applied as an attachment of a show-case, it being composed of foldable and detachable parts which adapt it to be extended vertically above the show-case for use, or partly dismembered and folded on the back of the show-case in such manner as to remove it from view.

TRUSS.—L. L. BAKER, Denison, Texas. This invention refers to trusses and is particularly useful in connection with devices intended for the alleviation or cure of abdominal hernia. The aim is to provide a truss in which the pads are resiliently secured to the frame of the device. Further, to provide a truss to which may be removably secured abdominal wings, and, if necessary, a suspensory.

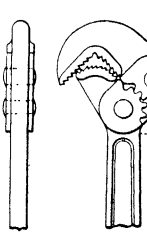
BALANCING TANK.—L. F. RIGOT, Milford, Pa. This inventor seeks to provide a tank suitable for use upon flying machines and the like, for carrying hydrocarbon fuel used for furnishing power for the machine, the parts being so constructed and arranged that as the liquid is gradually used up and consequently the tank becomes lighter, the center of gravity of the tank remains in its original position relatively to the framework of the machine.

EYEGLASSES.—L. B. BECKER, New York, N. Y. The purpose in this case is to provide improvements in eyeglasses, whereby the pivoted nose clips can be readily placed in position on their supporting studs or removed therefrom and interchanged with a view to locate the nose clips nearer to or farther from the bridge, as required or desired by the user.

PNEUMATIC ACTION.—HERMAN MEYER, New York, N. Y. This improvement refers to self-players, self-playing pianos and like instruments, and its object is to provide a pneumatic action having a bleed hole adjustment to permit accurate and quick regulation of the diaphragms and valves from the outside, with a view to insure proper opening and closing of the pneumatics.

AUXILIARY STOPPING DEVICE.—HERMAN MEYER, New York, N. Y. This invention relates to piano players, self-playing pianos and like instruments, and the inventor provides a device more especially designed to enable the performer to stop the motor quickly while playing and when music calls for a rest, and without the performer changing the position of the tempo lever or removing his hand therefrom.

TRADE MARK FOR A LUBRICATING OIL FOR MACHINERY.—J. A. FLEMING, Room 308, No. 328 Chestnut Street, Philadelphia, Pa. Mr. Fleming has adopted and used this trade-mark for a lubricating oil for machinery, in Class 15, oil and greases. The trade-mark is applied or affixed to bottles containing the lubricant by placing thereon a printed label on which the trade-mark is shown.



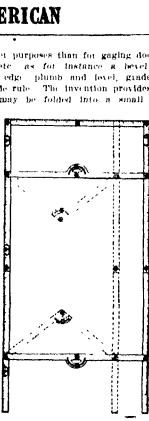
MOUSE TRAP.—J. LAQUERSTROT, New York, N. Y. An object here is to provide a means to kill the rat or mouse at the time it is caught. The trap is simply constructed and has few parts which might get out of order. It is set by opening a hinged cover, drawing a closure open against the action of a spring and holding the closure by engaging a bracket with a lever, which in turn is held by a bait holding lever.

MOLDING FLASK.—L. J. KEMPFFBERG, Easton, Pa. An object of this inventor is to provide a flask made up of a number of copes said copes being fastened together so as to form practically a unitary cope with means for fastening the cope thus made to the drag. A further object is to provide a novel form of fastening means so that the several parts of the flask may be quickly clamped together or unclamped, as occasion demands.

STUMP BURNER.—F. P. RAND, Spokane, Wash. This is an improved device for use in burning the bodies and roots of stumps both dry and green. It enables a stump to be destroyed quickly and easily without the use of any dangerous explosive, while the construction is such that it may be easily manipulated and may be produced at small cost.

Hardware and Tools.

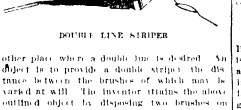
WRENCH.—F. W. FRITCHEY, Sandusky, Ohio. This wrench has a fixed jaw and a movable jaw, the latter being so connected to the handle that when it is pulled to turn a pipe, rod or other contrivance the act of pulling not only exerts a leverage on the handle but also exerts



WRENCH.

a leverage action on the pivoted end of the movable jaw, causing the hold of the wrench to be tightened. The wrench is shown in side elevation in the accompanying engraving. It is simple in construction and efficient in action. It can be cheaply manufactured and is well adapted for all purposes to which tools of this description are applied.

SAW TOOL.—D. R. WILLIAMS, Whittemore, Mich. One of the objects of this inventor is to provide a simple and inexpensive saw tool by means of which the jointing or aligning of the teeth of a saw can be effected rapidly and easily, and by means of which the cleaner or raked teeth of a saw can be filed down uniformly to any desired point.



DOOR GAGE.—CARL E. ROSE, P. O. Box 194, San Diego, Cal. An object here is to provide a gage which may be extended in either direction and which is provided with means for marking the position of the hinges, etc., as for instance a bevel square, straight edge, plumb and level, grade finder, and slide rule. The invention provides a scale which may be folded into a small compass

DOOR GAGE.

when not in use, and one having a novel form of marking device. The engraving herewith represents a side view of one embodiment of the invention the level and marking device being applied thereto.

DOUBLE LINE STRIPER.—HOWARD F. KING, Somerville, Conn. This invention is illustrated herewith in a perspective view. The improvement relates to a form of double line stripers for use more particularly by carriage painters for striping the wheels and bodies of carriages, automobiles, wagons or in any

DOUBLE LINE STRIPER.

other place where a double line is desired. An object is to provide a double striper the distance between the brushes of which may be varied at will. The inventor attains the above outlined object by disposing two brushes on a support, and by means of a rack and pinion movement, separate the brushes as desired.

PLATE LIFTER.—JOSEPH F. WEYMAN, New Philadelphia, Pa. The accompanying engraving represents the plate lifter in a perspective view. The invention relates to a form of lifter or detachable handle for articles especially those which are too hot to be readily handled without the interposition of some such tool. The object is to provide a utensil having parts, which may readily be constructed from metal wire, without the use of any connecting pivots. The relative parts are so constructed

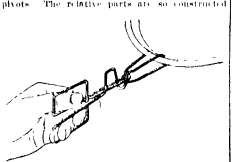


PLATE LIFTER.

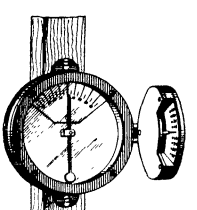
that they may be mutually traced and the parts are so constructed that they may be readily and removably locked in position. In the construction each member is made continuous of one length of wire, and there are no drilled joints.

BLADE HOLDER.—PAUL R. BUCHHOLZ, care of Chattanooga Med. Co., Chattanooga, Tenn. In this instance the invention relates more particularly to a holding device for flexible

BLADE HOLDER.



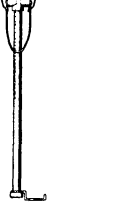
blades such as are used in safety razors. It will securely hold a blade in position for shaving or stropping. The blade is shown in the illustration herewith inserted in the holder. This is done by merely flexing it sufficiently to enter the slot and then pushing it in as far as it will go. It may be removed therefrom by pressing against the inner, upper corner, of the blade, with one finger, thereby swinging the blade outwardly above the lower corner thereof as a pivot.

Heating and Lighting.

LAMP.—F. M. EULER, Elizabeth, N. J. This invention relates to an adjustable and quick-detachable incandescing lamp. An object is to provide a lamp of any suitable type such as an incandescent lamp in which the lamp proper and in this case the bulb is adjustable to a plurality of angles whereby the light may be directed to any desired point.

Machines and Mechanical Devices.

LISTING INDICATOR.—JOSEPH ARNST, 516 North Clark Street, Chicago, Ill. The accompanying view is of an indicator constructed and arranged in accordance with the invention, the same being shown in conjunction with a stanchion for an aeroplane. The invention provides an instrument with indicators having visible scales and indicating members mov-



LISTING INDICATOR.

able thereover to show the lateral list of such a machine as an aeroplane and simultaneously the pitch of said aeroplane on its median transverse axis; provides an instrument the bodies of said index member being arranged in vertical planes, the last being perpendicular, and provides for the indicator being folded into compact form.

Pertaining to Vehicles.

WAGON BOX FASTENER.—HARRY F. BARR, Broken Arrow, Okla. This invention is an improvement in wagon box fasteners and its object is the provision of a simple inexpensive and easily operated device for use in holding the units of the box ready together without injury to the same which may be quickly applied or removed. The accom-

WAGON BOX FASTENER.

panying illustration shows the fastener in its front view. The device consists essentially of a pair of telescoping members or bars, each having a clamping jaw at its outer end, co-operating with the jaw of the other member and a clamp for holding the members at sections in adjusted position.

Designs.

DESIGN FOR WALL PAPER.—H. WARNE, Rixdorf, Alsace, Germany. In this ornamental design for wall paper the entire width shows a streaked effect interspersed with slightly undulating dotted lines composed of small square white dots.

DESIGN FOR AN IMAGE.—H. C. ANDERSON, Pensacola, Fla. In this ornamental design the image is a mechanism of a dog in the complete costume of hat, suit and shoes of the French court type of Louis XIV.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No publication will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12561) W E W Y says On the evening of September 7th, at 7 30 o'clock, there appeared a beautiful lunar rainbow in the western heavens. At about 7 P M a dark cloud arose in the west, and rain fell heavily for some minutes. It was perfectly clear in the east, and the full moon, coming up from the under world shot its rays through the rain drops with the result of a gorgeous rainbow at night. This is the first time a phenomenon of the sort has been observed here, so far as investigation discloses. Are there many instances of lunar rainbows on record? A Lunar rainbows are not a frequent occurrence. This one seems to have been unusually brilliant. Generally but a few colors are seen. The moon on September 7th was within one day of the full, and hence gave almost the maximum of light. This would account for the brightness of this lunar bow. The noted geologist Edward Hitchcock, formerly president of Amherst College, Massachusetts, once said in an address, "He who has seen one total eclipse of the sun or one transit of a planet over the sun, or one November shower of meteors or one spectral comet, or one lunar iris or one volcanic eruption, may be satisfied and cannot hope for a second sight." The writer of this note has seen all of these grand phenomena of nature, excepting a meteor shower of the first rank and a great volcanic eruption but he has had the privilege of seeing a lunar iris on two occasions and has seen volcanoes in action and many smaller meteor showers. The geologist was right in his list of rare natural phenomena.

(12562) F R K says I desire to copper plate glass plates 20 inches by 26 inches for use as a condenser in wireless telegraphy. Will you please give some method of coating the glass to render it a conductor, and also give voltage necessary? A glass may be prepared for copper-plating by giving it a coat of copal varnish or of gutta percha in benzole. When this is dry it will take plumbago in the ordinary way. Copper plating with an acid bath requires from 0.5 to 1.5 volts. With a cyanide bath 2 to 5 volts are needed. Various processes and formulæ will be found in Watt's "Electro Plating," price $4.50. It would seem necessary to have some good manual at hand for the numerous details of the work. It would be much easier for a novice to coat the glass with silver, as in a mirror. This process is fully described in our SUPPLEMENT 1071, price ten cents. The silver surface would be just as effective as a copper coating. The silver could be plated with copper. It might be the easiest way to obtain a base for the copper plating to deposit a thin coating of silver on the glass and plate the copper upon that.

(12563) W A S asks Have you a STATEMENT that will give detailed information in regard to magnetizing magnets such as are commonly used on such magnetos as are used for gas engine ignition? A Unless one has a practical knowledge of electricity at his disposal, it would be better to send magnets away to be magnetized. The process however is simple. A coil of wire should be made of such size that it will slip over the magnets so that the magnets may be passed through the coil. No. 16 B & S single cotton covered copper magnet wire may be used and 100 turns will be sufficient. Wind in concentric layers passing back and forth. This will make a coil about an inch and a half long and less than a half inch deep. If much be permanent use. It should be well filled with turns and should be for taking it from the form or wound upon which it has been wound. It should also be secured from unwinding, by binding it with fine cord. This coil will stand the passage of one or more little time without overheating. For most convenient use it may be connected in series with an electric motor circuit. It cannot be connected directly to lighting circuit its resistance is too small and coil would get hot in a few seconds or the fuses would be melted out. Pass the current to be charged through this coil every time. A small current will give you the polarity of the coil and magnet.

(12564) A D asks Can you give me a formula to make a solution to do electro silver plating with wet batteries. A A solution for silver plating may be made by obtaining 3 ounces of silver chloride and 6 to 12 ounces of potassium cyanide per gallon of water. The mode of preparation and the care of the bath are fully given in Van Horne's "Modern Electroplating," which we will send for $1. It is quite as important to keep the bath in good condition as it is to have it right at the outset.

NEW BOOKS, ETC.

YELLOW FEVER AND ITS PREVENTION. A Manual for Medical Students and Practitioners By Sir Rubert W. Boyce, M.B., F.R.S. New York. E. P. Dutton & Co. 1911 8vo; 380 pp., illustrated Price, $3.50 net.

The distinguished author of "Yellow Fever and its Prevention" has had exceptional opportunities for the observation of this scourge in New Orleans, Central America, the West Indies and Africa. His high standing in pathology and tropical medicine gives the volume an authority which no student or practitioner can afford to ignore. Many will recall his previous work, "Health Progress and Administration in the West Indies," in which was sketched the history of yellow fever in the West Indies and Central America. The present work deals more particularly with the scourge as observed in West Africa, although its general history and geographical distribution are first given. In succeeding divisions the disease is discussed from the viewpoints of symptomatology and treatment, pathology, epidemiology, and entomology, while not the least interesting and perhaps the most practical division is the closing one, under the head of prophylaxis. In this division a successful plan of campaign is drawn, which includes prompt official notification of the danger, the enforced retirement of non-immunes to a place of safety, and the attack upon the breeding grounds of the *Stegomyia*, the evacuation and fumigation of infected bungalows and the perforation of gutters. Plates, maps and five charts elucidate the text and add materially to its value.

GAS ENGINES By W J Marshall and Capt H Riall Sankey, R E New York D Van Nostrand Company, 1911 8vo, 278 pp., Illustrated Price, $2 net

"Gas Engines" is addressed primarily, not to designers and manufacturers, but to purchasers and users, that they may gain a better understanding of the possibilities and peculiarities of the internal-combustion engine and so secure more satisfaction and profit in its use. The intending purchaser is given information that will guard him against impossible claims for power and economy. The theory of the subject is carefully set forth, with the fundamental principles of its thermo-dynamics. The descriptions of typical cycles are accompanied by that wealth of illustration which is absolutely necessary to thorough instruction in any complicated device. The operation of the engine is given the space and consideration worthy of its importance. Gas and gas producers form the subject of the final chapter. The work is a very condensed and satisfactory presentation of a subject of universal interest.

MATHEMATICS FOR THE PRACTICAL MAN By George Howe, M E New York D Van Nostrand Company, 1911 12mo; 143 pp. Price, $1.25 net

The author has been impressed by the scarcity of published courses in the fundamentals of mathematics, and the tendency of these courses to treat the subject in a popular rather than a scientific way. The attendance of night schools is made up of such diverse bodies of men, of such varying degrees of training or lack of training that instruction must always begin with studies adapted to the lowest number of the students. The textbook in hand is designed to meet the requirements of night classes in that it begins at the beginning, assumes no mathematical knowledge beyond arithmetic on the part of the student, and strives to eliminate the vagueness and diffuseness of the average elementary work. It contains the fundamentals of algebra, the first principles of trigonometry, logarithms and the elementary principles of coordinate geometry and of the calculus.

LES LOIS EXPERIMENTALES DE L'AVIATION Par M. Alexandre Sée, Ancien Elève de l'Ecole Polytechnique Paris Librairie Aéronautique, 1911 8vo, 348 pp., Illustrated

M. Sée's papers constitute a thoughtful and well arranged presentation of the laws governing the science of flight. The five divisions of the work are "The Laws of Air Resistance," "The Theory of the Aeroplane," "The Flight of Birds," "A Study of the Propeller," and "The Problem of Stability." The conclusions at which the author arrives, and the expression of these conclusions in principles and equations, occupy far too much space to be summarized here. But the work will well repay study, and should be in the library of all experimenters. It is characterized by its Parisian reviewers as a remarkably clear and complete exposition of flight and the laws by which flight is governed.

RAND-MCNALLY OFFICIAL INDEXED POCKET MAPS AND SHIPPERS' GUIDES New York Rand, McNally & Co., 1911. Price, 25 cents each

We are in receipt of the following pocket maps and guides: Alberta, Colorado, Florida, Illinois, Indiana, Manitoba, Massachusetts, Mexico, Michigan, Minnesota, Newfoundland, New Jersey, New York, Ohio, Oregon, Saskatchewan, Texas and Washington. These are detailed and very legible maps showing the steam railroads and proposed extensions, with all stations and junctions plainly indicated. Electric roads are given in red. The new divisions and boundary lines, and the new post offices and express offices, are entered. Population, based upon the figures of the latest Census, is given for every city and village. Shippers, travelers, Civil Service students and others will continue to appreciate the cheap and handy form of this up-to-date information as they have done in the past.

ELECTROPLATING. By Henry C. Roets. Chicago: Popular Mechanics Company, 1911. 12mo.; 99 pp.; Illustrated. Price, 25 cents.

This treatise describes the process of electroplating and tells how to make a small outfit with a glass fruit jar and a wet battery. The more advanced phases of the subject are also entered, with a description of shop equipment and specific directions for nickelplating, silverplating, and goldplating, and a chapter of suggestions that may aid in establishing the beginner upon a business basis.

THE WHISTLER BOOK. A MONOGRAPH OF THE LIFE AND POSITION IN ART OF JAMES MCNEILL WHISTLER. Together with a Careful Study of his more Important Works. By Sadakichi Hartmann. Boston. L. C. Page & Co., Inc., 1910. 12mo.; 272 pp

The art of Whistler is very much in the public eye in this country at the present time owing to the remarkable Whistler exhibition which was held last year in the Metropolitan Museum. The writer is admirably equipped to perform most difficult task. The illustrations are admirably chosen and are beautifully executed, being printed on coated paper, the illustrations are inserted. Like all the books in this series, it is beautifully printed and bound.

WOOD-WORKING FOR AMATEUR CRAFTSMEN. By Ira S. Griffith. A.B. Chicago Popular Mechanics Company, 1911. 12mo.; 121 pp., Illustrated Price, 25 cents

The student first taught the care of tools, the laying out of rough stock, and the uses of the plane and the saw. Several simple objects are then pictured, such as a bird box an umbrella stand a table, a cabinet and in taking the beginner through the details of their construction further knowledge of the handling of tools and material is easily and naturally imparted.

THE BOSTON MUSEUM OF FINE ARTS By Julia DeWolf Addison Boston L. C. Page & Co., Inc., 1910 12mo., 454 pp.

The present work gives a descriptive and critical account of the treasures of the Boston Museum of Fine Arts which represent the arts and crafts of remote antiquity to the present time. A work of this kind is of the greatest possible value, as it can be taken right into the gallery, where it serves as an amplified catalogue to the collections in the Boston Museum of Fine Arts are too well known to call for any praise. The collection has been admirably made and is admirably housed particularly in the new buildings. The illustrations in the book are widely selected and are beautifully reproduced and printed. Like all the books of this publisher, it is an excellent piece of book making and is attractively bound.

MOLDING CONCRETE CHIMNEYS, SLATE AND TILE ROOFING By A. Houghton New York The Norman W Henley Publishing Company, 1911. 61 pp Price, 50 cents

This handbook is No 4 of the series, and is explanatory of the ways in which roof tiling and chimneys are manufactured of concrete. The text is fully illustrated by original drawings, and in this, as in the other numbers of the series, a feature is made of easily consulted models. The factor of safety has been steadily kept in mind.

MOLDING AND CURING ORNAMENTAL CONCRETE By A A Houghton New York The Norman W Henley Publishing Company, 1911 58 pp Price, 50 cents

This No. 5 of the "Concrete Workers" series, tells the proper proportions of cement and aggregates for different finishes, with the methods of mixing and placing in the molds, and of curing and remedying defects in the finished work. Also the manner of coating the molds with non adhesive compound to prevent the concrete from sticking to the molds.

TRAIN RULE EXAMINATIONS MADE EASY By G. E. Collingwood New York: The Norman W Henley Publishing Company, 1911 19mo; 234 pp. Price, $1.25

PRACTICAL INSTRUCTOR AND REFERENCE BOOK FOR LOCOMOTIVE FIREMEN AND ENGINEERS By Charles F. Lockhart New York The Norman W. Henley Publishing Company, 1911 12mo.; 362 pp Price, $1.50.

UP-TO-DATE AIR-BRAKE CATECHISM. By Robert H Blackall New York: The Norman W Henley Publishing Company, 1911 12mo.; 362 pp Price, $2.

These three books are of the practical kind that will appeal to men who are actually engaged in railroading. Mr Blackall's "Air-Brake Catechism," which has long been a standard work, describes the air-brake equipment and how it is operated. Mr Lockhart's book is a text book for locomotive engineers and firemen. Mr. Collingwood's book is in the nature of a quiz, and follows the question and answer method. The three books may be recommended for giving a vast amount of information in a very compact form.

ISOMERIC SETS. By Dr. Charles Frederick Bolduan. New York: John Wiley & Sons, 1911. 238 pp. Price, $1.50.

It is probably safe to say that in the scientific world there are few subjects of greater importance, as far as the great public is concerned, than that of the bacteriological treatment of diseases. The advances made in this field, particularly during the past few years, have been greater, or at least as great as, those in any other field of research. Naturally a subject which touches the well-being of the race so closely as this has provoked a widespread interest, not merely in the medical profession, but throughout every walk of life. Because of the highly scientific character of the investigations and achievements of the bacteriologist, his work is not easily explained, and is difficult of understanding, not merely by the average citizen, but even by many practitioners who are greatly occupied time prevents them from keeping in close touch with the progress which has been made. Consequently, there has been a call for a work on the subject which would be accurate, simple and concise, yet sufficiently comprehensive as a clear understanding of what has been done and of the reasonable expectations of future progress.

In the work under review, Dr Bolduan appears to have successfully met this need. The present volume is the fourth edition of the work which first appeared in 1904, and which dealt only with certain anti-bodies, whose discovery had aroused a great deal of scientific interest. To this was added in subsequent editions a discussion of anti-toxins, agglutinins, opsonins, all of which were naturally embraced under the title "Immune Sera." In the present edition the scope of the subject matter has been widely extended, and the work contains a clear exposition of the main facts of infection and immunity. Every one who has been sufficiently interested to read even cursorily the broader literature on this subject is familiar with the side-chain theory of Ehrlich, which of late years has dominated the investigations in this particular field. While admitting the value of Ehrlich's work, the author considers that some of the deductions from his theory have led to conclusions which are opposed to plain established biological facts. Therefore, in giving a lengthy presentation of Ehrlich's views, he makes it clear just why and wherein other investigators have differed from him. Of particular interest at the present time is a chapter dealing with the principles underlying the treatment of syphilis with Salvarsan, or 606, as it is popularly called. The value of this drug is now generally conceded, and leads one to hope that further work along similar lines will sooner or later bring to light specific therapeutic agents in other diseases.

Those of our readers who have followed the newer conceptions of physical chemistry will be interested to see how quickly and extensively these have been taken up by the workers in this fascinating department of medicine.

Dr. Bolduan has succeeded in fulfilling the aim of this work, which is to present a lucid, clear outline of the main facts and theories concerning infection and immunity. An excellent feature of the book is the fact that it is presented in clear, concise, and forceful English that is not overburdened with technical phraseology.

THEORIE PHYSICO-CHIMIQUE DE LA VIE ET GENERATIONS SPONTANEES By Stéphane Leduc Paris: A Poinat, 1910. 8vo; paper

In the introduction to his remarkable book, Prof. Leduc states that the essential phenomenon of life is nutrition. If food is to be assimilated, it must be introduced in the liquid state; hence the elementary phenomenon of life is the contact between alimentary liquids and living substances, and the knowledge of life is subordinated to the knowledge of the physico-chemico phenomena which result from the contact of different liquids. Biology, in Prof. Leduc's opinion, is destined to be a part of the physical chemistry of liquids. The physical chemistry of life, therefore, comprises a study of all non-electrolytic solutions and electrolytic solutions, of colloidal solutions, of molecular forces at play in these solutions, osmotic pressure, crystallization, and the phenomena produced by such forces as diffusion and osmosis.

THE TENNESSEE SHAD. By Owen Johnson. New York: The Baker & Taylor Company 12mo.; 310 pp.; Illustrated. Price, $1.20 net.

When Owen Johnson's "The Varmint" first immortalised the American preparatory school as a few classics had immortalised the so-called "public schools" of England, nor the least inspired episode was that of the Tennessee Shad's "sleep prolonger" and its exploitation by Doc Macknoder. Doc, it will be remembered, so skillfully engineered the financial end of the business as to divert to himself all the profits of the enterprise. In this later story the Tennessee Shad's imagination continues to efferesce, and the development of Macknoder's business instincts is calculated to make a pall-bearer chuckle. Johnson's boarding of school themes is delicious and intimitable.

LEGAL NOTICES

OVER 66 YEARS' EXPERIENCE

PATENTS

TRADE MARKS DESIGNS COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions, Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the oldest agency for securing patents; it was established over sixty-five years ago.
